PURGATIVES AND MALNUTRITION

The dangers attending the administration of irritant purgatives to delicate and debilitated patients have long been recognised

Whilst a certain amount of immediate relief may be thus obtained the disturbing effect on the autonomic nervous system and the malnutrition resulting from irritation of the absorptive mechanism frequently outweigh the temporary alleviation There appears also, to be considerable risk of malnutrition in the constant use of laxatives of the so called lubricating type The covering of the mucous membrane of the intestines with a thin coating of oil can hardly fail to lessen the absorption of aliment Moreover it was found by Channon and Collinson that a portion of the mineral oil is liable to be absorbed and to accumulate in the liver The pathologic possibilities of such accumulation need no stressing

For the relief of moderate degrees of constipation in cases in which the fullest nutrition is important no safer or more reliable laxative can be found than an effervescent preparation of the standard of Eno's "Fruit Salt

In Eno's "Fruit Salt it is claimed, we have at our disposal a carefully compounded, pure and standardised preparation entirely free from the harsh and disagreeable sulphates of soda and magnesia Eno's 'Fruit Salt has been used and prescribed by thousands of doctors for over half a century, during which time its reputation has become world wide

PARKE DAVIS & CO

ADRENALIN

The Product of Unique Experience

PARKE DAVIS & Co introduced Adrenalin to the medical profession in 1901 well tried preparation—is extracted from the medullary portion of selected adrenal glands. The isolated substance is then standardised by both physiological and chemical methods to secure full activity of the finished preparation.

During the thirty years that have elapsed they have manufactured it continuously and their long experience has convinced them that Medical men can make sure of obtaining natural Adrenalin possesses many advantages Adrenalin that is potent uniform in action over the synthetic product and reliable by specifying P D & Co Adrenalin (P D & Co)—the original and

Full particulars of Adrenalin (P D & Co) and its uses in medicine will be sent on request. Adrenalin Chloride Solution P D & Co is supplied in bottles and ampoules. Hypodermic Tablets Inhalant Lozenges Suppositories Ointments and Adrephine (Adrenalin Ephedrine Combined) are also available

PARKE DAVIS & CO BEAK STREET LONDON W 1

[REGISTERED AS A NEWSPAPER

ISSUED WEEKLY]

The debilitated patient and the athlete

are alike in one respect—they both need

(a) immediately accessible energy i.e., glucose

(b) elements to nourish and control their nerve cells and reflexes i.e., calcium & phosphorus

(c) vitamin D to ensure the assimilation of these elements

Glucose-D contains all these components

Whenever glucose is prescribed, whether for the treatment of acidosis or febrile illnesses or as a "nutrient tonic" for debilitated or overstrained adults and children, Glucose D, the reinforced glucose, is the preparation of choice

ANTIVIRUS THERAPY

LABORATORY INVESTIGATIONS have shown that bacteria cannot grow in filtrates of their own broth cultures The inhibitory substance is called Antivirus

CLINICAL EXPERIENCE has shewn that local infections heal rapidly when antivirus made from the responsible or associated organisms is applied to them In practice antivirus acts not only as a specific antiseptic but as a means of increasing the resistance of the body cells at the site of infection

THE APPROPRIATE ANTIVIRUS brings about the rapid healing of boils carbuncles abscesses sinuses infected wounds and septic cavities It can be applied by means of a spray or on lint to any accessible local infection

ANTIVIRUS THERAPY is easy and effective

In the every-day routine of ordinary clinical practice

LIVOGEN

The blood-regenerating tonic

On account of its value in the process of blood regeneration Livogen is now widely prescribed in the every-day routine of ordinary clinical practice for the treatment of a variety of conditions of blood impoverishment

Livogen is of particular value in the many forms of secondary anaemia in anaemias of pregnancy in the malaise following severe illness and in fact in all debilitated conditions

The remarkable results that follow the administration of Livogen are attributable to the fact that it contains the haematopoietic principles of fresh liver together with Vitamins B_1 and B_2 in standard sed amounts and haemoglobin

How Gibbs Educational Service promotes the interests of the Doctor

The Gibbs Ivory Castle Game

Another very effective piece of propaganda which has just been introduced is the Gibbs Ivory Castle Game —a most fascinating and amusing game with a plain moral for all who play to learn

The game interests young and old and keeps the question of oral hygiene well to the fore-front of general conversation—even in playtime hours This lighter phase of the Gibbs Educational programme combines very pleasingly with the more serious efforts

Full particulars of Gibbs Educational Services (literature, propaganda material, cinema films, lecture charts and other school-room aids) as well as clinical samples for tests, are gladly sent free upon request to any member of the Medical or Dental Profession on receipt of professional card

The confidence of the MEDICAL PROFESSION

Benger's Food has gained its unique position not by extravagant or sensational claims but by the constant recommendation of Medical Practitioners

Benger's Food is scientifically prepared to adjust fresh cows milk diluted or undiluted to suit the individual requirement of the patient In this respect it is distinct from any other food obtainable

Benger's Food is largely used as a routine treatment in all cases of impaired digestion The following comments recently made by Doctors indicate some specific conditions in which the Medical Profession prescribes Benger's Food

DYSPEPSIA

routine food in all cases of dyspepsia and disordered digestion

used for invalids and all gastric cases

INFLUENZA

very largely used for Influenza in all its forms

CANCER

invaluable for cancer of the throat"

cancer of the stomach—doing well on Benger's Food

. . gratifying results in the treatment of

LEUCORRHOEA *(incipient and chronic)*

Physicians are invited to apply for full particulars and clinical sample to the manufacturers

Very gratifying results have attended the use of Monsol Pessaries in the treatment of both incipient and chronic leucorrhoea, and in kindred catarrhal conditions

Prepared on a glyco-gelatine base containing the equivalent of 2½ % Monsol in a colloidal form, Monsol Pessaries are actively germicidal in the presence of organic matter, absolutely NON-CAUSTIC to the delicate tissues, and deeply penetrating These properties are doubtless the explanation of their success in combating these conditions

CONTRAMINE

In the chronic stage of disease

Contramine is of value in the chronic stage of disease where the signs and symptoms presented are caused by the hydration of the protein particles in the plasma Contramine has the effect of causing dispersion of these enlarged hydrated particles The drug is one of the best antidotes against metallic intoxication it is of particular value also in cases of chronic rheumatism arthritis and fibrositis whatever be the origin

Contramine is supplied in ampoules which contain the drug in sterile aqueous solution ready for intramuscular injection it is issued also in pessaries for the treatment of gonorrhœa and leucorrhœa in women

Literature and samples on request

THE BRITISH DRUG HOUSES LTD LONDON N-1

Digitalin Granules "A. & H."

gr $\frac{1}{240}$ ($\frac{1}{4}$ mg)

gr $\frac{1}{600}$ ($\frac{1}{10}$ mg)

Digitalin Granules, "A & H," a British preparation, consist of the *Digitaline cristallisee* of the French Pharmacopœia. This substance is the most active principle of digitalis leaves and, because of its reputation for uniform activity, it has long been popular, particularly on the Continent. Its use is recommended by high authority in cases where galenical preparations of digitalis have failed.

For Prescribing
In tubes containing 40 granules 2/6 each
For Dispensing
In bottle containing 250 granules 12/6 each
Subject to the usual professional discount

Valentine's Meat-Juice

IN Debility, Nervous Exhaustion and Anæmia, where Digestion is Impaired and it is Essential to Conserve the Weakened Vital Forces, Valentine's Meat-Juice demonstrates its Ease of Assimilation and Power to Restore and Strengthen

Employed in many Hospitals and Sanitariums and recommended by many leading Physicians and Surgeons throughout the world

Physicians are invited to send for Clinical Reports

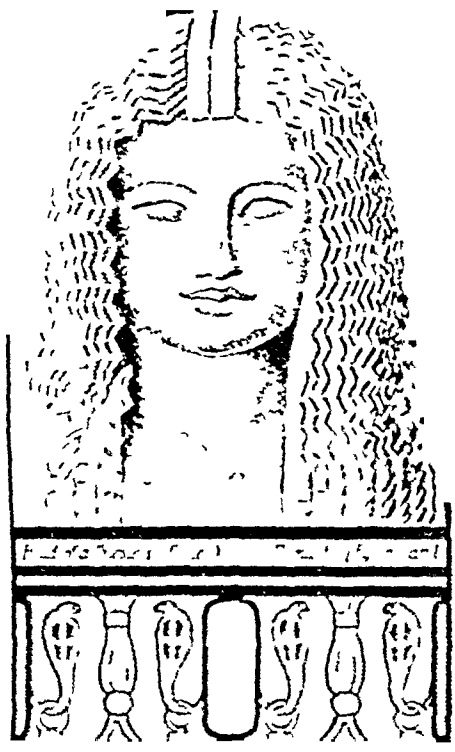
For sale by European and American Chemists and Druggists

Valentine's Meat-Juice Co., Richmond, Vir., U.S.A.

OVALTINE

FOR THE AGED

Ovaltine is delicious sustenance for old people It sustains life ideally by giving tone to the tissues and promoting the healthy activity of the bodily functions



Ovaltine provides complete nourishment in easily assimilable form Its use greatly increases the nourishing value of other foods The digestibility of milk for instance so largely used in old age is increased two fold by adding Ovaltine to it while the starch in the cereals is converted into easily assimilated malt sugar by the extensive diastase which Ovaltine contains in abundance

Ovaltine is purin free Its use therefore neither aggravates nor favours the accumulation of uric acid in the system or leads to kidney disorder or gout The tendency to corpulence so common in old age is avoided by the use of Ovaltine

Ovaltine replaces to great advantage the usual table beverage tea tea coffee which are valueless as sources of nutriment and often contraindicated in senility

A liberal sample for trial will be sent on request

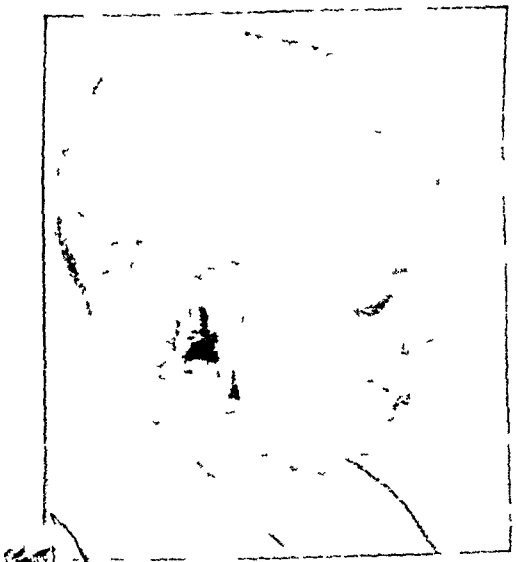
AN ADEQUATE SOURCE OF VITAMIN B

Physicians are daily becoming more impressed with the value of BEMAX in the treatment of PARTIAL Vitamin B deficiency, of which the common symptoms include Indigestion, Constipation, and Lethargy, associated with gastric and intestinal atony, leading to Intestinal Stasis

BEMAX

THE NATURAL VITAMIN TONIC FOOD



BEMAX is a preparation of the detoxicated embryo of selected cereals carefully stabilised It contains 500 units of Vitamin B (complex) per ounce (Sherman method) It provides a bland tasty food easily assimilated by patients of all ages A tablespoonful daily provides adequate Vitamin B to restore nutritional balance in an adult BEMAX is very economical a 2/6 carton lasts an adult one month

Vitamin B cannot be stored within the system so BEMAX should be taken regularly when definite results should be observed

Laboratory reports on BEMAX and a full size carton for clinical test will be sent to any physician on receipt of his professional card

Heporite

Trade Mark Reg.

A Tonic Restorative containing the haemopoietic principles of mammalian liver (Hepatex), haemoglobin, glycerophosphates, iron and the vitamins B1, B2 and C

Heporite is well adapted for use during convalescence after exhausting illness and for debilitated conditions generally. In the impairment of function resultant upon Secondary Anæmia it provides the stimulus necessary to prevent the contraction of other disease which may prove more serious than the original trouble.

It is also particularly suitable as a tonic for weak and debilitated children.

Issued in 8 oz. bottles

Local Anæsthesia in Surgical Practice

REDUCTION OF FRACTURE.

Typical Case

J K M aged 12 years

Diagnosis Fracture of the right radius and ulna

Operation Reduction of fracture—closed method

Anaesthesia *Transverse infiltration block, 40 cc of 1 per cent Novocain Adrenaline solution being used*

Operation A transverse block was immediately made at a point 5 cm above the line of fracture The fractures were reduced—a moulded plaster splint was applied and the boy allowed to return home with his mother

NOTE —*This case is mentioned to illustrate certain point The child's mother was a widow without funds The child came to the surgery during usual hours on a busy afternoon The necessity for preparing him for General Anæsthesia as well as the necessity for employing an ambulance for sending the child to the hospital the amount of time required in order to carry out the necessary treatment were factors which entered into the handling of the case Under the plan mentioned above a transverse block anæsthetized the arm the surgeon reduced the fracture and the assistant then applied the necessary dressing The total expenditure of time by the surgeon was less than five minutes Furthermore the child left the surgery travelling on his own power From an economic standpoint the use of Local Anæsthesia in such cases presents many advantages*

EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Fifth)

(Full technique of this and one Hundred other operations under Local Anæsthesia will be found in the above work published by Henry Kimpton 263 High Holborn London W C 1)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals Specify "Novocain" for your next operation

Does not contain Cocaine, and does not come under the Dangerous Drugs Act

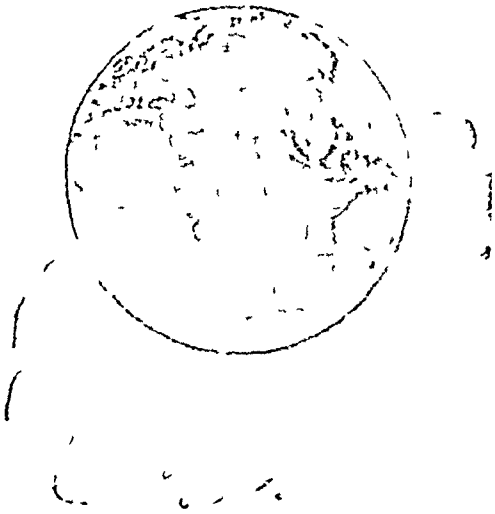
NINTH PERIOD—1926 TO 1936

Ergot Idealised—

TRADE 'ERNUTIN' MARK

Presents Ergotoxine (the specific alkaloid of ergot) as the Ethanesulphonate, together with 'Ergamine' and 'Cornamine,' in definite amount and in a state of chemical purity



For Oral Administration
"ERNUTIN" ORAL
Contains Ergotoxine Ethanesulphonate 0·033 per cent
Boxes of 30 cc. 4/-, 100 cc. 10/6, 250 cc. 25/-, 1/1 fl. oz.

For Intramuscular Administration
"ERNUTIN" HYPODERMIC
Contains Ergotoxine Ethanesulphonate 0·1 per cent
Boxes of 1 c.c. ampoules (each equivalent to 0·1 c.c. of 1 in 10) of 5 at 2/6, 10 at 4/-, 1 fl. oz.

"WELLCOME"
ERGOTOXINE ETHANESULPHONATE

The most stable salt of Ergotoxine. More soluble than the phosphate. Ergotoxine Ethanesulphonate was originated and introduced by Burroughs Wellcome & Co.

Full particulars on request

Leukoplast

The Plaster chosen by the Profession throughout the World

3 Characteristics
have given to LEUKOPLAST its world-wide reputation

1. Prompt Adhesion

A Leukoplast strapping adheres immediately wherever it is placed Light pressure for an instant suffices to ensure close and lasting adhesion to the skin

2. Reliable Durability

A Leukoplast dressing remains in position just as long as desired It will not become dislodged through movement, strain or body-warmth

3. Freedom from Irritation

Leukoplast will cause neither rash nor irritation even to very sensitive skins, as special attention has been paid to this point in the process of manufacture

For the Tropics

Particular qualities best suited to definite climatic conditions are always supplied

Free samples on request

A Paper
ON
THE ORIGIN OF TUMOURS *
BY
J P LOCKHART MUMMERY M B B CH F R C S

I am one of those who have maintained for many years that the secret of tumour formation which has for so long eluded us lies somewhere in the study *of the normal* tissue cells and that we cannot find the explanation by studying tumour tissue There have been a great many theories put forward to explain the origin of tumours but none of them have fulfilled the necessary conditions Any theory of tumour genesis must be able to explain certain well established facts Every fact must fit into the theory and if it does not then either the fact is wrong and is not admissible or the theory is false and must be abandoned *or modified*

PROPERTIES OF TUMOURS

I shall now briefly state what appear to be established facts about tumours which any theory of their aetiology will have to explain

1 Tumour cells grow by their own division and not by converting neighbouring cells into tumour cells

2 The tumour cell is specific to its original character wherever it may be Thus the cells of a tumour which started in the rectal epithelium retain the character of rectal epithelium *even if they are growing* in the liver in the brain or in a bone

3 Tumour cells are species specific Thus human tumour cells will not grow in any other animal

4 Not only are tumours species specific but there are a very great many different kinds of tumours for any single species and for each different tissue We classify tumours according to the tissue in which they originate but the tumours of the same tissue show great differences Some grow faster than others *some are more* resistant to radium some tend to degenerate etc some to regress and while some secrete others do not It is seldom that two tumours are met with which are really identical in every respect

5 Tumours can be produced by a great many different agents such as tar some aniline dyes cobalt sunlight heat lime (as in betel nut chewing) chronic sepsis (as in varicose ulcers of the leg and in septic sinuses) parasites (as in cancer of the stomach produced in rats by *Spirotera neoplastica* and in men by the ova of bilharzia) radium and x rays and the cell free filtrate which produces the Rous sarcoma There are in fact a very large number of carcinogenetic agents but there is no common factor between them

6 Where there is a known cause of tumour formation acting at a certain time there is evidence that a latent period occurs before the appearance of the tumour This latent period is a very constant factor in the genesis of tumours

FACTORS INFLUENCING CELL CHANGE

Tumour cells do not differ from normal cells in histological structure and isolated tumour cells cannot be distinguished from the normal cell of the tissue in which they arose unless their altered relationship to the neighbouring cells and more particularly to the cells of the connective tissue can be seen In fact tumour cells are normal cells which are behaving abnormally It is the behaviour of the cell and not its apparent structure that differentiates it from the normal cell from which it arose It seems probable that all the cells of the body reproduce themselves at certain times in order to replace cells which have become worn out or old There is a beautifully exact *adjustment to the requirements of the tissue concerned* and it seems certain that every cell in the body is subject to some control as regards its behaviour and that the chief controlling mechanism resides in the cell itself It is true that the behaviour of any cell may be profoundly modified by its environment and by factors outside the cell Hormones from the thyroid the pituitary the gonad the adrenal and many other glands affect the behaviour of whole groups of cells Hormones or similar substances *from other cells* also affect the cell s behaviour as is seen in the repair of injuries but the response of the cell to these various factors is fixed and its behaviour is primarily determined by its own inherent controlling mechanism which is inherited from the germ cells from which it originally arose The individual cell is much like a human being it may be greatly altered by its surroundings its nourishment and hosts of other factors but its inherent character and the way in which it will *respond* to *different* factors in the environment is determined by the genes it has inherited from its ancestors When we find that a cell or a small group of cells is behaving in a radically different manner from its neighbours in the same area we are forced to conclude that some radical change has taken place in the nucleus of the cell

ANALOGY OF GERM CELL

We can now attempt to visualize the nature of this controlling mechanism which resides within the cell but in order to do so we must refer to our knowledge of the germ cell in which the behaviour of the cells can be studied most easily We know from recent biological studies that every *human cell* contains twenty four pairs of chromosomes within its nucleus that each chromosome contains a vast number of genes and these genes control the behaviour under every possible condition of every cell wherever it may be situated

When one germ cell unites with another germ cell of the opposite sex to form the fertilized germ cell which will ultimately become the foetus this fertilized germ cell will contain in its nucleus a complete double set of twenty four *chromosomes* (in the case of man) nd a complete set of genes from both the original parent cells The genes in this cell will control after *differentiation has* commenced what the daughter cells will become in the developing foetus whether they become muscle cells nerve cells bone cells epithelial cells or connective tissue cells and how they will behave so long as they exist and will even determine their life cycle

Now if this is true of the germ cells—and no one disputes it—then it must be equally true of the somatic cell It seems impossible to argue otherwise It must not be overlooked that the somatic adult cell also reproduces itself There are two distinct forms of reproduction of cells reproduction by fertilized germ cells and partheno genesis of ordinary or somatic cells Individuals develop according to the characters they inherit from their parents and in the same way the tissue cells develop according to the characters *they* inherit from *their* parents The parent or *father* of every *cell* decides the character and behaviour of the daughter cells and this is just as true of the somatic cells as it is of the *germ* cells There are two kinds of inheritance the inheritance of the germ cell and the inheritance of the somatic cell In the recognition of this fact lies the explanation of tumours We know from studies of the germ cells that a change can occur in the nature of the genes of a germ cell from influences in the environment and therefore extrinsic to the cell itself Such a change in a gene is

* Read at the inaugural meeting of the Harley Medical Society London March 10th

called a mutation, and when a mutation occurs the gene or genes concerned will continue to breed true to the mutation or change which they have undergone. It is believed by most biologists at the present day that accidental gene mutation has been largely responsible for the evolution of new species by giving natural selection changes selectively to protect advantageous mutations.

Theory of Gene Mutation

If a gene mutation can occur in a germ cell or a cell which is going to become a germ cell then it can also occur in a somatic cell and the consequences though not the same, will be similar.

Let us attempt to visualize what may happen if an epithelial cell is exposed to some external influence which results in a mutation to one of the genes within its nucleus. Such a cell will when it next undergoes mitosis pass on to its daughter cells the mutated genes and there will be a change in the behaviour of the daughter cells as compared to the parent cell from which they originated. If we suppose that the mutation is a bad one then the daughter cells will be at a disadvantage and will probably not survive for long or will die at once and the mutation will cease to exist as happens when a bad mutation takes place in the germ cells. If on the other hand the mutation is one which is not necessarily disadvantageous or which gives one definite advantage to the daughter cells the mutation will tend to persist during the life of the organism of which the cells containing the gene mutation form units. Should the gene mutation be one for excessive reproduction—that is to say reproduction in excess of the normal rate for that particular cell—it is obvious that the daughter cell which will result when that cell next undergoes mitosis will be at a considerable advantage as compared with the other cells around them and will tend to increase abnormally at the expense of the surrounding cells. In other words the beginning of a tumour will have resulted. The cells in the mutated colony will be normal cells except that their rate of reproduction will be faster. This is exactly what a simple adenoma or papilloma of epithelial tissue is found to be.

Its Application to Somatic Cells

It will be argued that no experimental evidence of gene mutation in somatic cells is forthcoming, and that we are not justified in accepting such a theory without experimental proof. Yet there are many phenomena which cannot be investigated by experimental methods. Fortunately Nature is continually doing experiments herself and if we are sufficiently observant and can correctly interpret the results of her experiments it is sufficient to establish the truth. Gene mutation in somatic cells cannot be proved by experimental laboratory methods at present.

This theory or hypothesis of tumour genesis explains how it is that an apparently normal cell becomes parasitic upon its neighbours. It explains the essential difference between a tumour cell and a normal cell and if it is correct it must explain all the facts with regard to tumours that are known to be true. Any agent that produces a gene mutation in a somatic cell may result in the production of a tumour if the mutation affects the genes so as to increase the normal rate of mitosis. We know from the study of genetics that gene mutation can be produced in many different ways which have no apparent connexion with each other and that under natural conditions gene mutations do occur and have been occurring throughout the history of life since they are one of the chief causes of variation in species. Mutations in germ cells have been produced artificially in several different ways. Thus Morgan produced a gene mutation in the fly *Drosophila* by heavy doses of x rays and Mottram produced gene mutation by exposing the flies to the beta rays of radium and by exposing the female *Drosophila* to CO. It is certain that gene mutation can be produced by very many different agents and if tumour formation is due to mutation of somatic cells it is understandable why we find such diverse agents with carcinogenetic properties.

Such a theory of tumour genesis explains why tumours grow by division of their cells and not by converting the neighbouring cells with which they are in contact into tumour cells. It is perfectly understandable on this theory as the mutated cells which form the tumour only differ from the normal cells in that they have an excessive power of growth but there is no way in which they can convey their power to other cells except by inheritance to their own daughter cells. The intensely specific character of tumours is immediately understandable. A gene mutation must breed true and a cell containing a gene mutation will breed true to the mutation as long as its somatic life exists. An epithelial cell in the mucous membrane of the intestine having undergone mutation of its genes to excessive or abnormal rate of growth becomes in time the parent of a mass of similar epithelial cells which have the power of abnormal growth and these offspring of the mutated parent cell will become a tumour. The cells composing it will always retain their characters of intestinal epithelium wherever they may be. Their transplantation into the liver brain or bones is an accident resulting from their excessive growth but in no way alters their specific characteristics. Their growth rate and their fate may be profoundly altered by differences in blood supply in the character of their connective tissue connexions and other factors resulting from the change in their environment but they will retain the characters of the parent epithelial cell from which they arose. This theory explains the enormous variety and complexity of tumours which may arise even from the same tissue and a great variety of tumours is what we should expect depending upon the particular tissue in the cells of which the mutation occurred and the particular genes in the nucleus which have mutated.

Critical Examination of Theory

There is a marked hereditary factor in cancer incidence and breeding experiments have shown that by selective breeding this factor can be greatly increased. Thus in some strains of mice bred by Loeb the cancer rate was as high as 90 per cent of those who reached the cancer age while in other strains it was zero. These experiments all refer to mammary cancer in the females only. All the breeding experiments on hereditary factors in the aetiology of cancer have shown that the factor which is inherited is not cancer or tumour formation itself but tumour formation in certain cells of a certain tissue—in Loeb's experiments the mammary tissue of the female mouse. The obvious deduction is that the hereditary factor is an hereditary tendency for the cells of some particular organ or tissue to become tumorous. It does not seem unreasonable to suppose that by selective breeding the cell nuclei of some particular tissue may become more liable to mutation of their genes than the tissues of animals in whom there has been no such selective breeding. It seems certain if this theory is correct that mutations of somatic cells which do not concern the reproduction of the cell must also occur and many diseases besides tumours can probably be explained in this way. Many of the melanotic and keratotic changes in the skin are examples of somatic cell mutation and it is probable the leukaemias can also be thus explained.

Many people have for a long time thought that the explanation of tumour formation lay somewhere in the biology of the normal tissue cell but it was not until the

Cancer Conference in London in 1928 that the possibility of a mutation of the nucleus of the somatic cells began to be considered seriously It was suggested by Loeb Teutschlaender Strong and Mayor but no definite theory was propounded, as most investigators were more concerned with the pros and cons of the infective theory of Gye Ten years ago Theodor Boveri the zoologist put forward the theory that cancer is due to abnormal mitosis —tetrapolar mitosis—of the cell nucleus resulting in an abnormal number of chromosomes He had got the same idea as he attributed tumour formation to genetic changes in the cell nucleus but this theory was not generally accepted because the tumour cell according to his theory must have a wrong number of chromosomes There is considerable evidence that the nucleus of the ordinary tumour cell contains the correct number of chromosomes and that tetrapolar mitosis is at any rate quite uncommon in tumour cells The whole subject has been much confused by the fact that tumour cells are often found with all sorts of abnormal nuclear structure but there is every reason for believing that the ordinary tumour cell is quite normal as regards its chromosomes and that gene mutation and not multipolar mitosis is the primary factor in tumour genesis More recently in 1930 R J Ludford gave an excellent resume of the whole subject but it did not receive the attention it deserved

The strongest argument for believing that this theory of tumour genesis is the true one is that it is possible by means of it to explain all the different phenomena that have been observed in tumours and their behaviour No other theory has made it possible to interpret all the observed facts about tumours and as the facts are seen to fit in and come into line as it were the inference becomes very strong that the theory is correct How it will help in solving the problem of the cure of tumours which to us as doctors is of more importance remains to be seen At first sight it looks as if it will not help at all But experience in medicine and surgery has taught us that when the cause of a disease is known we are in a fair way to discovering how to prevent or cure it Cause and effect are a natural sequence and if we know the cause it cannot but help towards the ultimate goal of full control over this great class of diseases which we call tumours and which hitherto we have been so comparatively helpless in attacking successfully

SUMMARY

1 The essential difference between a normal cell and a tumour cell is one of behaviour not of apparent structure The tumour cell grows faster than the normal cell

2 There are two kinds of reproduction—that which produces a new individual and that which results in the replacements of injured or worn out cells in our tissues

3 All cells both germ cells and somatic cells breed true to their parent cells and this breeding is controlled by the genes in their nuclei

4 Changes or mutations of the genes in the nuclei may occur and when they do the daughter cells will always breed true to the mutation

5 Tumours are the result of a mutation of the genes controlling division of somatic cells

A NOTE ON THE OPERATIVE TREATMENT OF FACIAL PALSY

WITH AN ACCOUNT OF SOME ANIMAL EXPERIMENTS

BY

SIR CHARLES BALLANCE KCMG LLD MS FRCS

CONSULTING SURGEON TO ST THOMAS'S HOSPITAL

The experimental inquiry on which the following notes are based was carried out by Dr Arthur B Duel and myself at Laurelwood Dutchess County New York State during the years 1930 and 1931 A full account of the experiments is printed in the *Archives of Oto Laryngology* January 1932

Each anastomosis operation was combined with the removal of the facial nerve from the aqueduct of Fallopius Sometimes on gentle traction on the central end of the divided facial nerve 3 cm of the nerve came away This was followed by escape of cerebro spinal fluid from the aqueduct The object in view was to prevent the union of the divided ends of the facial nerve which would vitiate the clinical results The stimulation of the facial area of the Rolandic cortex and of the nerves in the posterior fossa of the base of the skull was undertaken as a routine in the final examination of each experimental animal

The grafting of the hypoglossal descendens noni or glosso pharyngeal nerve to the facial nerve in man is followed as recovery takes place by associated movements during eating and swallowing Whether such movements ever disappear we do not know but while they last they are disfiguring and distressing to patients during meals When in our baboons one of the above nerves was united to the facial associated movements were observed during the fourth month from the date of the experiment and they continued without remission till the animal was killed When a sensory nerve—for example auriculo-temporal—was grafted to the facial nerve no associated movements were expected and none were observed The spinal accessory nerve was not employed in the anastomosis experiments because in the many cases we had observed in man the contraction of the muscles of the face was associated with the contraction of the sterno mastoid and trapezius muscles This is a great disability Further there is deformity of the neck and maybe drooping of the shoulder The contraction of the muscles of the face dissociated from that of the shoulder muscles the movement most desired is seldom if ever attained even many years after operation

OPERATIVE TREATMENT OF FACIAL PALSY

GENERAL CONSIDERATIONS

There can be no question about the desirability attending an anastomosis operation or about the imperfections present in many cases that were hailed as good recoveries in the past. After all it is an unnatural thing to anastomose one nerve to another when the ideal surgical method of bringing the two ends of a divided nerve into contact either directly or by means of a nerve graft is both feasible and practicable. We therefore removed portions of the facial nerve from the Fallopian aqueduct and substituted for the portion of the nerve taken away in equal length of some other nerve. For example we have used the descendens nomi nerve the intercostal nerve the intercostal nerve and the external respiratory nerve of Bell from the axilla. We prefer to take the nerve graft from the nerve of Bell in the axilla there is something rather pleasing about curing Bell's palsy with Bell's nerve.

The graft operation in the Fallopian aqueduct causes recovery from facial palsy far more rapidly than any anastomosis operation and cannot of course be followed by associated movements. We collegue Dr. Dalziell write us that he has already done in his hospital alone twelve nerve graft operations for facial palsy and that the earliest are all on the way to complete recovery.

Many cases of facial palsy recover only in part after prolonged medical treatment by massage and electricity and there often the victims of a spontaneous spasm of the most acute. The spontaneous spasms have been observed in a few of the baboon both after anastomosis operations and after nerve graft operations. They are not uncommon when an experimental animal is under light anæsthesia. The nerve impulses the cause of the spontaneous spasm originate at the level of the corpus striatum and not in the cortex. They are described under the term paleokinetic in contradistinction to cortical spasm in the cortex which are called neokinetic. The spontaneous tic spasm is more prone to occur after an anastomosis experiment than after a nerve graft operation. We believe that early operation and perfection in the technique of the nerve graft operation are the pathways which lead to the avoidance of spontaneous spasm of the recovering face muscles.

The following account gives three examples of the experimental results.

ANASTOMOSIS OPERATIONS

Case I

Baboon operated on August 17th 1930. Glosso pharyngeal facial end to end anastomosis (right side) facial nerve removed from aqueduct of Fallopius.

The glosso pharyngeal nerve exposed till the petrous ganglion came in sight was divided just before its two terminal branches (motor and sensory) entered the muscle in front. The central end was turned backwards and united to the peripheral end of the facial nerve which had been severed at the stylomastoid foramen.

Examination of the animal 357 days after the operation at rest during eating and when angry showed equal movement in the occipito frontales. The right palpebral fissure was smaller than the left. Winking was synchronous and equal in range. Movements of the nose were equal on both sides. Mouth fissure was normal and lip movements equal in extent. Associated movements during swallowing were noted as follows: retraction of right ear partial closure of right eyelids and right angle of mouth pulled backwards. There was no spontaneous spasm.

With the animal anæsthetized faradic and galvanic current gave an equal response of all muscles on both sides of the face. Under light anæsthesia there was a spontaneous twitch of the muscles of the right upper and lower lips and the angle of the mouth was pulled backwards. No spontaneous spasm was observed except when the animal was lightly anæsthetized. The spontaneous spasm was synchronous with spasm of the eyelids. There was also a tonic contraction of the muscles of the posterior third of the right side of the tongue which appeared to be synchronous with the winking spasm. Stimulation of the facial area of left Rolandic cortex gave a normal response in the muscles of the right side of the face.

When the brain was removed and the nerves in the posterior fossa of the base of the skull stimulated the right facial nerve gave no response. The right glosso pharyngeal nerve gave good contraction of the muscles of the upper and lower lip and retraction of angle of mouth. With stronger current the right eyelids closed.

Stimulation of right glosso pharyngeal nerve at lower border of jugular foramen (petrous ganglion exposed) caused contraction of all muscles of the right side of the face.

The above is an excellent example of an anastomosis operation with the usual associated movements.

Case II

Baboon operated on August 23rd 1930. Auriculo temporal facial end to end anastomosis (right side) facial nerve removed from aqueduct of Fallopius.

The auriculo temporal nerve was exposed on the zygoma above and in front of the auditory meatus. It was followed underneath the attrahens auriculam muscle and divided at the upper border of this muscle. The central end was turned downwards and united to the peripheral end of the facial nerve which was exposed at the stylomastoid foramen.

Examination 145 days after the experimental operation with the animal at rest eating and when angry gave the following results.

The eyelids winked together equally. The nose was straight. The right food pouch was used. Mouth normal. When teeth were shown the pull of the left upper lip was a little stronger than the right. There was no spontaneous contraction spasm or associated movements.

With the animal anæsthetized the faradic and galvanic current gave an equal response on both sides in all muscles. Under light anæsthesia there was a spontaneous twitch of the muscles of the right upper and lower lips synchronous with the winking spasm. These spasmodic movements did not take place except under light anæsthesia. Stimulation of facial area of the left Rolandic cortex caused normal contraction of all muscles of the right side of the face.

When the brain was removed and nerves were stimulated in posterior fossa of the base of the skull the right facial nerve gave no response and the right fifth nerve caused contraction of all muscles of the right side of face.

The auriculo temporal is a small sensory nerve. Nevertheless its anastomosis with the facial nerve resulted in recovery from complete facial palsy in this experiment. No associated movements are possible.

NERVE GRAFT OPERATION IN FALLOPIAN AQUEDUCT (RIGHT SIDE)

Case III

Baboon operated on September 16th 1930. Seven millimetres of the facial nerve in Fallopian aqueduct were replaced by 7 mm. of the descendens nomi nerve. After 160 days there was no sign of deformity of face when the animal was eating an apple. Under anæsthesia faradic and galvanic current gave an equal response in muscles of the right and left sides of the face—including occipito frontales.

Examination 325 days after operation showed complete recovery of the right side of the face with no spontaneous spasm.

No spontaneous spasm when under anæsthesia equal response to faradic and galvanic stimulation on right and left sides of face. Stimulation of the facial area of left Rolandic cortex produced contraction in all muscles of the right side of the face. Stimulation of right and left facial nerves in the posterior fossa after removal of brain produced equal and full contraction of muscles of the right and left face.

This experiment is an example of the rapid and complete recovery from facial palsy when a nerve graft is substituted for a similar length of the facial nerve in the aqueduct of Fallopius. Moreover no associated movements are possible and in this case no spontaneous spasm occurred.

OSTEO-ARTHRITIS *

BY

MATTHEW B RAY D S O M D Ed

SENIOR PHYSICIAN TO THE BRITISH EMPIRE CANCER CAMPAIGN FOR RHEUMATISM

In seeking a working classification of the various forms of chronic arthritis perhaps the best way of clarifying our ideas on this vexed question is to regard all kinds of joint disease as falling within two main categories *specific* where the aetiology is known and *non specific* or *rheumatic* where it is still largely undetermined Under the former would be placed cases due to trauma or associated with the presence of a known infective agent such as the tubercle bacillus the gonococcus the spirochaete the pneumococcus or the typhoid bacillus The second or rheumatic group may again be divided into two kinds one primarily involving the joint surfaces and endarticular and the other affecting in the first instance the tissues round the joints and therefore periarticular The terminology of the first being anatomical is more discriminating than the second which has received such names as rheumatoid arthritis infective periarthritis and atrophic and focal arthritis The two varieties are sometimes combined under a common title of arthritis deformans a term which is rather falling into disuse The reason for this confused nomenclature is that observers are not agreed upon a common basis for classification Some view the conditions from an anatomical standpoint while others are concerned with problematical aetiological considerations It is only in the earlier stages of these diseases that hard and fast distinctions can be drawn because in the later stages of the second variety changes characteristic of osteo arthritis may be superadded

ANATOMICAL FEATURES

The changes in osteo arthritis can best be considered as they affect (*a*) the articular cartilage (*b*) the underlying bone and (*c*) the synovial membrane and capsule

The Articular Cartilage

The central portion of the articular cartilage is the furthest away from the circulus articuli vasculosus from which is derived the rich network of capillaries which supply the perichondrium of the lateral parts Those more centrally situated are supposed to draw their nourishment mainly from the synovial fluid direct Achard points out that a study of the morphology and physiology of the articulations shows them to consist of actual and potential spaces within mesoblastic elements and as Hare says these connective tissue spaces of microscopic dimensions are enlarged into articular cavities bursae and tendon sheaths All are formed from the same elements and all contain transudates from the blood plasma the percentage composition of which varies slightly according to the variations in the functions of the different spaces It is easy to see therefore that toxins however derived once in the blood stream have a ready access to the articular cartilages It is at this poorly nourished weight bearing portion of the cartilage that the changes in osteo arthritis first manifest themselves The same irritant that will cause proliferation of tissue elements in a well nourished part of the body will set up degenerative changes in a part that is poorly supplied with blood

The most characteristic appearance presented by the cartilage in the early stages is the condition known as fibrillation which according to Timbrell Fisher is preceded by parallel and vertical striae in pathological specimens these can be felt by the finger The deeper layers of the cartilage may be invaded by vascular ingrowths of osteoblasts forming new bone These ingrowths may result in rounded elevations with smooth surfaces to which Professor Shattock gives the name of epiarticular ecchondroses to distinguish them from the periarticular ecchondroses forming the well known lipping of the joint The epiarticular ecchondroses often become detached and give rise to loose bodies in the joint Following the degenerative changes in the more central portion of the cartilage the lateral portions which have a better blood supply proliferate and project outwards This lipping of the cartilage eventually becomes ossified by osteoblasts from the underlying bone and constitutes the familiar osteophytes At a later stage the cartilage gradually becomes eroded and on disappearing reveals the underlying bone which undergoes sclerotic changes and becomes eburnated As pointed out by Gilbert Scott the formation of osteophytes occurs early in the progress of the disease and the erosion of cartilage much later Thus early formation of osteophytes and the late disappearance of cartilage are important diagnostic features because in rheumatoid arthritis and chronic infective arthritis erosion of cartilage takes place at a much earlier stage

Changes in Underlying Bone

As the new formations beyond the articulating surfaces are recurved there is not usually that limitation of movement in the early stages which might be expected Impairment of movement in an osteo arthritic joint early on is generally due to the fact that the joint has not been put through its full range of movement at regular intervals The layer of bone immediately under the articular cartilage is thicker and denser than normal When the overlying cartilage finally disappears the exposed bone becomes polished and glistening The gradual wearing away of the bone causes marked shortening of the limb One may occasionally see irregular processes of bone projecting into the deep surface of the cartilage The periosteum near the articular margins may proliferate and form bony nodules (periosteal osteophytes—Heberden's nodes) Beneath the sclerosed bone the cancellous spaces have an unusually open and fatty texture Radiographic films often show cyst like cavities surrounded by a zone of bone stimulation and protective sclerosis The precise nature of these cysts has not yet been determined The formation of osteophytes is really purposive and directed towards compensation for the loss of the central articular surface

Changes in Synovial Membrane and Capsule

These usually follow lipping of the articular surfaces The membrane becomes thickened along with the proliferation of the synovial villi At a later stage hypertrophy of the villous processes becomes very marked This is more particularly seen in the knee joint and some observers have given it the name villous arthritis The synovial villi are occasionally the seat of chondromata which may be single or multiple and which may undergo mucoid degeneration with the formation of cystic cavities When these chondromata become free in the joint they constitute one variety of loose body With regard to the changes in the capsular and interarticular structures the capsule becomes thickened and adherent and the various interarticular ligaments may disappear altogether This results in deformity joint instability and even dislocation The same applies to the various tendons situated in the neighbourhood of or passing through the joints In some instances the tendons may even acquire new attachments—true ankylosis practically

* Address given to a combined meeting of the Folkestone Medical Society and the British Medical Association January 21st 1932

never occurs All limitation of movement is due to alterations in the shape of the articulation and the interlocking of the later osteophytes

Aetiology

Osteo arthritis unlike rheumatoid arthritis is much more of a local than a general disease Its subject are usually well nourished robust individuals of a somewhat plethoric type The two most important aetiological factors are age and trauma It is essentially a disease of late middle life when early degenerative changes first make their appearance According to Glover (Report on Chronic Arthritis p 18) the typical age of onset of osteo arthritis (monarticular) is at least two decades later than rheumatoid arthritis With regard to sex incidence the hip and spine are more prone to be affected in men and the knee in women

A history of trauma can be obtained in most instances under the term trauma are included not only bruises and injuries to joints but any long continued stress or strain That form of arthritis which is especially prone to affect women at or near the menopause is often due to the increase in weight at the time which subjects the knees to extra strain Certain occupations are very apt to bring about the condition in individuals who by reason of their work are liable to joint strains Van Breemen terms this variety traumatic arthritis One may quote such well known examples as the labourers spine a form of osteo arthritis affecting the lumbar vertebrae stevedores and coal miners arthritis of the hip joint the labourers knee a form of osteo arthritis of the shoulder joint People who have to spend long hours on their feet frequently develop an arthritis of the medial joint which is often preceded by traumatic flat foot It is also common in horsemen of every grade of life and in these cases is not seldom associated with a more intractable sciatica due to the implication of the lumbar origins of the sciatic nerve by an extension of the process to the lumbar vertebrae is well as to the hips In such instances there may have been a fall from a horse (possibly several years previously) resulting in a more or less transitory injury which may have been quite forgotten until the patient begins to experience difficulties in performing certain movements

The association with a focus of infection is not nearly so apparent in this form of arthritis As Glover points out 75 per cent of the population over the age of 40 have septic teeth yet nothing like this proportion suffer from arthritis This is not to say that in the treatment of this condition every care must not be exercised to determine the presence of and to remove any possible focus But it is to say that the wholesale extraction of teeth as a routine procedure is unjustified This is abundantly borne out by the multitudes of edentulous patients one sees whose arthritic joints have been in no way benefited by the loss of their teeth A certain temporary alleviation is claimed which is explicable by the fact that people with sore mouths do not overeat Climatic factors have apparently very little to do with the incidence of osteo arthritis is the disease is found all over the world

Dampness of houses or sites is more likely to bring on fibrositis than arthritis but there are no reliable statistics on which to base a definite conclusion

Clinical Features

The duration of osteo arthritis having an insidious onset and not heralded by fever or constitutional disturbance is recorded in vague terms in case histories Its incidence is practically the same in both sexes Its comparatively late commencement has already been noted

Unlike rheumatoid arthritis the joints implicated are usually few and one or more larger ones are first involved The condition may remain monarticular throughout its course The initial changes are endarticular at first and result in a gnarled irregular outline which although resembling gout in some respects is quite distinct from the fusiform swelling seen in rheumatoid and infective arthritis Apart from sudden locking movement is at first very little interfered with and bony ankylosis never occurs What is called the jam-neck syndrome is absent This is an early involvement of the temporo maxillary joint accompanied by pain stiffness and grating of the back of the neck it is considered by Herbert as pathognomonic of rheumatoid arthritis General wasting of the limbs only takes place in the terminal stages although as will be seen subsequently certain muscles atrophy early on The skin over the joints does not show that atrophy and waxy appearance so characteristic of the rheumatoid condition There is no pallor shows nothing of importance The blood picture shows nothing of importance There is no anaemia and the suspension stability is not markedly lowered The uric acid content of the blood may or may not be increased The radiographic changes will be referred to in dealing with the individual joints

Following a general clinical description some consideration must now be given to the individual joints more commonly involved

Finger Joints

As the finger joints are implicated in practically every kind of arthritis the importance of being able to distinguish the various changes cannot be too highly stressed Outgrowths from the epiphyseal ends of the phalanges are extremely common in elderly people especially women Heberden's nodes as they are termed besides being unsightly may be very tender and painful on their first appearance They can be distinguished from the tophi of gout by the fact that they are firmly attached to the bone while the gouty nodule is capable of slight movement The nodes are of very little clinical importance and may persist for years without causing any marked inconvenience except perhaps in the performance of some of the finer movements of the fingers No treatment is of any avail Real osteophytes growing out wards from the articular surfaces of the fingers are quite common and by their position cause gross deformities The distal phalanx may be tilted to one or other side at almost a right angle This is more especially seen in the terminal phalanges Besides the irregularity of the articulating surfaces the capsule of the joint undergoes fibrotic changes which further increases the pull For this reason many writers speak of a fibrous rheumatism or rheumatism sicca which is characterized by the appearance just mentioned The first and second metacarpo phalangeal joint may be affected but is usually more thickened than deformed The distinguishing features of an osteo arthritic finger joint are its irregularity in contour its asymmetrical distribution and no real ankylosis—although owing to its osteophytic outgrowths there may be locking and limitation of movement There is not as a rule that peculiar doughy feeling on palpation due to distension with synovial fluid Muscular contractures are not common and the over extension of the proximal phalangeal joints with the fixation and flexion of the distal phalangeal articulations is absent

The Wrist

An arthritis of the wrist especially when there is much synovial effusion is more likely to be infective or rheumatoid The possibility of a gonococcal infection should not be forgotten

The Elbow

Blacksmiths are liable to an osteo arthritis of the elbow joint from the wielding of a heavy hammer It is characterized by pain on movement stiffness creaking and a liability to locking in certain positions It is not a common affection

The Shoulder Joint

A ring or collar of osteophytes may in advanced cases be found surrounding the head of the bone This will of course seriously interfere with its normal movement on the scapula In such cases it will be found that in all movements at the shoulder the two bones move together Fixation of the scapula will cause a corresponding immobility in the humerus On looking at the shoulder on the affected side considerable muscular wasting will be noticed A history of some antecedent trauma can usually be elicited or the joint may have been subjected to long continued strains in occupational cases

The Spine

Buckley divides spondylitis into two main divisions—namely spondylitis ankylopoietica or ankylosing spondylitis and spondylitis osteo arthritica (the type concerning us here) The important factor in its causation appears to be heavy laborious conditions The primary change is probably in the intervertebral disks which undergo much the same changes as the cartilaginous surfaces of other joints Exostoses are thrown out to support the weakened joints These can be seen on x ray films and are in striking contrast to the bamboo-like appearance of the ankylosing variety Some degree of movement is always retained though there may be flattening of the lumbar curve and kyphosis in the dorsal region If the osteophytes happen to press on nerve roots pain may be very severe As a rule it is not marked except from strain from which it will recover with rest for a few days

The Hip Joint

Coxarthritis or malum coxae senilis is much commoner in men than in women It is essentially a disease of late middle life or old age The earliest symptoms are usually neuralgic in character Pain along the distribution of the sciatic nerve is complained of and it is extremely difficult at first to decide whether one is dealing with an incipient coxarthritis or a case of sciatica Soon however some limitation of movement is experienced—or rather certain ordinary movements give pain There is an increasing difficulty in lacing the shoes and sitting with the thighs crossed becomes impossible Pain is felt in the groin and in the neighbourhood of the trochanter and the patient cannot make long steps or ride in comfort Perhaps one of the most certain objective signs is early wasting of the buttock on the affected side This is followed by a general wasting of the thigh muscles When definite shortening has taken place and there is inability to abduct and adduct the limb and when flexion causes a flattening of the lumbar curve while rotation of the thigh is no longer practicable there is no doubt about the diagnosis

The x ray picture is very characteristic The purposive formation of osteophytes to which reference has already been made is particularly well exemplified in the hip joint One frequently sees a collar or fringe of osteophytes thinly covered with cartilage surrounding the head of the femur Bone may be deposited within the acetabulum and this can cause displacement of the head of the bone outwards Absorption of the acetabulum frequently takes place at a later stage This may cause a bulging inwards of the pelvic wall or by an extension of its cavity the head of the bone may travel upwards Before this occurs a distinct flattening of the contour of the femoral head can be made out The effect of weight bearing can best be seen in this joint

The Knee Joint

Osteo arthritic changes are commonly seen in the knee joint As its strength lies not in the anatomical peculiarities of the articular ends of the bone but in the toughness and resisting qualities of the complex structures which bind them together it is easy to see that from strains and relaxations of the muscles and ligaments faulty apposition of the bony components of the joint can readily be brought about Although both sexes are liable to the condition it is more common in women about the time of the menopause Llewellyn and Bassett Jones in their work on fibrositis refer to two stages in the life history of this type as it affects women (1) a primary or pre osteophytic stage often of prolonged duration whose clinical characteristics are those of villous hypertrophy and (2) a secondary or terminal stage in which bony and cartilaginous outgrowths make their appearance Some writers call this climacteric arthritis but its end results are osteo arthritic in character

In the early stages the knee creaks a good deal on movement This is often the first symptom the patient notices There is a fair amount of pain especially after walking Overuse may bring on a mild synovitis which clears up with rest These attacks become more frequent thickening of the synovial stratum takes place and boggy swellings can be made out on each side of the patellar ligament The muscles that control the knee joint—particularly the quadriceps—become flabby and may show distinct signs of wasting An important point to be remembered in connexion with an arthritis of the knee is that the plantar arches are frequently depressed and this may cause a faulty alignment in the weight bearing functions of the lower limb

The Foot

Perhaps the commonest form of osteo arthritis seen in the foot is found in association with the weaker flat foot where the longitudinal arch has failed and compensatory proliferation has taken place in the astragalus which shows a distinct bulging above the inner plantar margin The metatarso phalangeal joint of the great toe also commonly reveals osteo-arthritic changes What is known as the painful great toe joint is often due to hypertrophic outgrowths corresponding to Heberden's nodes in the fingers In many of these cases the anterior metatarsal arch is depressed and the toes are habitually dorsiflexed at the first phalangeal joint producing the hollow or contracted foot The weight is borne entirely on the heel and the front of the foot Callosities and corns usually form on the centre of the heel and beneath the heads of the metatarsal bones Patients often complain of neuralgic pain about the great toe the metatarsal area or in the sole of the foot This hollow or contracted foot is associated with arthritic changes in the knees to a much greater extent than is usually realized

Treatment

Although in many respects osteo arthritis may be looked upon as a local rather than a general disease the fact remains that its manifestations are associated with degenerative conditions Treatment must therefore be directed towards sparing the patient any unnecessary metabolic burden A good working rule to effect this is to estimate the calorific value of the ordinary diet the patient is in the habit of taking and to reduce it by one third This is especially applicable in the case of well nourished plethoric individuals which so many of the subjects are There is usually an increased blood pressure and the blood uric acid is apt to be high For this

reason the diet should follow very much the lines adopted for gouty patients. Besides avoiding foods rich in purins an adequate supply of vitamins should be ensured. This is of prime importance because osteo-arthritis is undoubtedly associated with the absorption of toxins from a sluggishly acting bowel. Good results frequently follow measures directed toward changing the character of the intestinal flora either by the use of Bulgarian soured milk or by such a preparation as lacto-dextrin (supplied by the Battle Creek Company).

Drugs.

So far as drug treatment is concerned the old-fashioned Chelsea pensioner—compound confection of guaiacum or its more modern prototype—tabloid guaiacum and sulphur co.—is of distinct value. It probably acts as an intestinal disinfectant. Lugol solution finds favour with many prescribers. In certain forms of glandular disturbance associated with the menopause thyroid medication is clearly indicated. For the local treatment of the synovitis accompanying arthritis of the knee nothing beats a Scott dressing. Although no specific can claim anything of the nature of a specific in the treatment of osteo-arthritis many patients undoubtedly derive benefit from it at times. This is probably accounted for by the change of application of diet and exercise and the placing of the patient in such an environment that the *vis medicatrix naturæ* can act to the best advantage.

Physical Methods.

In addition to the general measures briefly outlined above there are certain physical methods of treatment which are of the greatest value in preserving movement in affected joints and muscles and in the relief of pain.

For the first of these the deep pool bath is extensively used. It is of sufficient depth to allow a patient to stand upright and to walk a step or two and wide enough to permit exercise. Its temperature is kept at about 100° F. Combined with the pool is an underwater douche at a temperature of about 10° above that of the bath. This has a powerful effect on the skin circulation and as it often constitutes a very efficient form of massage as well as relieving pain. As all objects weigh less in water than in air a limb immersed in water can be moved with much less fatigue than in ordinary circumstances. The water supports the limbs and movements are permitted that would be otherwise impossible. In addition to the actual mobilization of a stiffened joint the fact that movement is possible at all has an excellent mental effect on the patient and he is thereby encouraged to persevere in his efforts. For the relief of pain heat in some form or another is a sovereign remedy. To be effectual it should be intensive or as hot as can be borne. It may be applied in various ways—the hot immersion bath with an underwater douche 10° higher than the bath radiant heat or the high frequency current (diathermy). In deep seated parts such as the hip diathermy is the method of choice. For local applications to more accessible parts the hot pack of peat mud or paraffin wax is of value. As owing to the immobilization of the affected joint the muscles which control it are apt to waste underwater massage and manipulation—given by either the Aix or the Vichy system—will restore their tone and at the same time remove effusions that are liable to form owing to the sluggishness of the blood and lymph circulation.

Active and Passive Movements.

Keeping in mind the dictum that no joint can possibly be healthy unless it is moved or, in other words unless it is functionally active the question naturally arises as to whether osteo-arthritic joints are to be kept moving. So far as possible movement should be maintained but it should be more passive than active. The degree of pain that attends such efforts is the best guide. It has been wisely said that in osteo-arthritis one should train up the osteophytes in the way they should go. This is not to say that in the acute stages of joint inflammation movements are to be forcibly carried out. At this period rest with soothing applications is essential. When as frequently happens walking sets up intense pain and interferes with the patient's general health the application of a calliper splint must be considered. Properly fitted such an appliance will save untold pain. It is inconvenient cumbersome and much disliked but the assurance can be given that in time it can be dispensed with. In the case of the hip with the cessation of the constant grinding of eburnated bone surfaces one upon the other the osteophytes interlock and the periarticular structures become fibrosed and add to the stability of the joint. Mobility is seriously interfered with but pain disappears and although the patient walks with a limp he is able to live in comparative comfort. The knee is somewhat different. Its strength lies in its ligaments and osteophytic outgrowths do not interfere to such an extent with the apposition of the articular ends of the bones concerned as is the case with the hip. They do of course limit movement but a patient can walk quite well with very little play between the two bones. After wearing a calliper splint for the knee for some time it is often found that on leaving it off there is still enough movement at the joint to permit walking without a perceptible limp. By cautious manipulation and the judicious employment of one or other of the methods of physical treatment briefly referred to above the range of movement may be considerably increased.

Operative Measures.

There will still remain however a certain number of cases in which neither physical methods of treatment nor fixation will relieve the intolerable pain. The question of operative intervention will then have to be considered. Such procedures have for their object either the correction of deformities by osteotomy or the removal of some intra-articular cause of arthritis—such as a misplaced semilunar cartilage or a loose body—or they may be designed with the aim of enabling the joint to be used without pain. This might entail the removal of osteophytes and an excision of the joint or an arthrodesis to secure bony ankylosis. In this connexion it must be remembered that cases of osteo-arthritis are by no means ideal subjects for extensive operative measures.

A CASE ILLUSTRATING FAILURE OF INTRAVENOUS LIVER THERAPY IN PERNICIOUS ANAEMIA

BY

J. G. McCRIE, M.B., F.R.C.P.Ed.

LECTURER IN MEDICINE, UNIVERSITY OF EDINBURGH; TUTOR IN CLINICAL MEDICINE, ROYAL INFIRMARY, EDINBURGH

It appears justifiable in view of the prominence recently given to the value in certain cases of pernicious anaemia of liver preparations suitable for intramuscular or intravenous injection [1 2 3 4 5 6 7] to record a single case in which this mode of therapy proved ineffectual though it is admitted that the data furnished are not sufficient to enable completely definite conclusions to be drawn.

CASE RECORD.

Female, aged 62, married. Admitted to the Royal Infirmary, Edinburgh (under the care of Professor W. T. Lithgow) on February 2nd, 1932 complaining of bloodlessness and pains all over of three years' duration, breathlessness for one year and loss of appetite for about two months.

No satisfactory medical history was available but it appeared that the patient had not been in good health for three years. She had noticed oedema of the feet and ankles especially in the evening during that period. Intermittent pain and stiffness in various situations—notably the back, belly and limbs generally—had made it difficult for her to get about, but these symptoms had not been so prominent during the six weeks immediately preceding admission as severe breathlessness on exertion had rendered the patient practically bedridden. For about two months towards the end of 1931 pain across the stomach relieved by vomiting had been present; the appetite thereafter became poor but pain and vomiting ceased. Soreness of the tongue was not complained of. There was no history of haemorrhage. The patient stated that she had lost weight. She gave a history of an operation for ovarian tumour forty years previously and of gall-stones twenty years previously, but in general appeared to have been a healthy woman up to the time of onset of the symptoms already described.

Apart from the fact that the patient was one of a family of fifteen of whom eleven died young, the family history revealed nothing of note.

Physical Examination.

General nutrition poor, but no gross emaciation. Some oedema of the feet present. Patient very pale with a lemon-yellow tint. Van den Bergh reaction positive, delayed direct. Icterus index 14. Pulse rate 108 per minute; blood pressure 114/64. Heart not enlarged; blowing systolic murmur audible all over praecordia, loudest in pulmonary area. Marked muscular weakness in lower extremities, but reflexes normal and sensation (including vibration sense) unimpaired. Tongue very pale, clean and smooth; no ulceration and no subjective soreness. Abdomen: scars of former operations present; otherwise nothing abnormal detected. On account of the patient's great weakness examination of the gastric juice was not carried out. Stools: no abnormal appearances; benzidine reaction for occult blood negative. Urine: healthy. Respiratory system: no abnormal signs detected.

Blood Examination.

Red blood cells 885,000 per c.mm.; haemoglobin 18 per cent. (Haldane); colour index 1·06; white blood cells 2,000 per c.mm. A second count gave the following figures: red blood cells 813,000 per c.mm.; haemoglobin 20 per cent.; colour index 1·25; reticulocytes 3·4 per cent. Anisocytosis was marked, megalocytic forms being prominent, many having the oval shape emphasized by Davidson and Gulland[6]. A Price-Jones curve was not constructed, but careful inspection of the film left little doubt that this would have been of the typical broad-based variety, with deflection of the summit to the right. There was some poikilocytosis. A few cells showed punctate basophilia; polychromasia was not seen. No nucleated red cells were observed even after extensive search. Platelets were obviously diminished; such as were present occurring singly rather than in groups. A differential count of 100 leucocytes gave the following result: neutrophils 64 per cent., lymphocytes 35 per cent., monocytes 1 per cent. In view of the unexpectedly high proportion of neutrophil, considering the leucopenia, another count was made by an independent observer on another film, with practically identical figures were obtained. Many of the neutrophils showed hypersegmentation of the nucleus, indicating a shift to the right of the polynuclear count.

TREATMENT AND PROGRESS.

From February 3rd to 9th (*inclusive*) the patient was given daily intravenous injections of 5 c.cm. of a liver preparation which has recently been the subject of favourable comment in the literature[1-4]. The seven dose is said to contain the active principle derived from 100 grams fresh liver. No undesirable effects appeared to be associated with the injection, but there was no improvement in the patient's general condition, and no reticulocyte reaction occurred. As already noted, the reticulocyte level was 3·4 per cent. on admission. On the second day of treatment the figure was 5 per cent., but thereafter a fall occurred, the reticulocyte percentage varying from day to day between 0·5 and 1·5.

On February 10th the patient's condition being obviously one of extreme danger, a blood transfusion was decided upon. Both the patient and the daughter selected as donor belonged to Group IV (Moss), the bloods were directly tested for incompatibility, and no agglutination was found. Shortly after the commencement of the operation, however, the patient became extremely distressed, restless and dyspnoeic. The transfusion was stopped immediately and stimulants given, but the patient died one hour later.

Post mortem Examination.

This was carried out on February 11th thirty-one hours after death, and the appearances typical of pernicious anaemia were found. There was a slight generalized yellowness of the skin, and the legs showed some oedema. The serous sacs contained a small quantity of clear yellowish fluid. The heart was slightly enlarged and globular in shape, the myocardium being pale and flabby, and showing in the region of the right ventricle considerable fatty infiltration. There was a slight increase of bright yellow subepicardial fat. The lungs were oedematous particularly at the bases. The mucosa of the stomach had a very atrophic appearance. The liver was enlarged and pale in colour. The spleen was enlarged, soft and bright red. The kidneys presented a pale yellow appearance. Apart from some oedema the brain showed no abnormality. In the centre of the shaft of one femur fat had been completely replaced by bright red erythroblastic marrow of diffluent almost creamy consistency; there was considerable erosion of cancellous bone. The first ribs also showed a marked erythroblastic reaction. The liver showed a definite Prussian blue reaction, the spleen and kidneys a fainter one.

Microscopical examination of the bone marrow revealed the presence of very active haematopoiesis, this having the characters described by Davidson and Gulland[6] as typical of pernicious anaemia. The erythroblastic areas showed definitely a megaloblastic reaction, many cells of very primitive type being seen. Equally characteristic was the large amount of leucopoietic tissue present; in these areas the predominant cell was the myelocyte, polymorphs were scanty and megakaryocytes also much reduced in numbers. The liver showed extensive fatty changes, the spleen packing with red corpuscles and the kidney slight arterio-sclerotic changes together with marked degeneration of the tubular epithelium. Professor G. Lovell Gulland was kind enough to consider fully all the facts of this case including the microscopical sections above described, and as a result had no hesitation in stating the case to have been one of pernicious anaemia.

COMMENTARY.

The question arises whether in this case the diagnosis of pernicious anaemia may have been wrong, though the opinion of Professor Gulland quoted above naturally renders this unlikely.

The clinical and pathological findings are admittedly compatible with this diagnosis. It remains to be discussed whether they are compatible with any other diagnosis. The post-mortem data put any kind of secondary anaemia out of court—a secondary anaemia of high colour-index type with leucopenia in any event a most unusual phenomenon. Leukaemia and acute lymphadenoma can be similarly excluded. Aplastic anaemia was at the end the diagnosis favoured clinically on account of the lack of response to treatment, but in view of the intensely active marrow demonstrated at necropsy was proved to be incorrect. The condition which appears most to warrant discussion is that of the obscure haemolytic anaemias group referred to by Davidson[5]. One imagines that certain of these cases would be regarded

by Lord Dawson[7] as examples of acholuric jaundice since he does not consider a normal blood fragility incompatible with this diagnosis and further states that while the marrow response in acholuric jaundice is usually normoblastic it may be megaloblastic with a high colour index type of anaemia Though the fragility of the erythrocytes was not investigated in the present case any such diagnosis appears to be ruled out by the co existence of a hyperplastic marrow with a low percentage of circulating reticulocytes In haemolytic anaemia death may occur in the presence of extensive marrow hyperplasia if blood destruction runs ahead of even markedly increased blood formation but in the circumstances the circulating reticulocyte percentage is high Conversely as emphasized by Lord Dawson death may result from dimin hed marrow output even though blood destruction may not be excessive but in these cases the small number of reticulocytes in the circulation can be shown at necropsy to have resulted from marrow hyperplasia Low circulating reticulocyte percentage and of the marrow cannot coexist (as they did in this case) unless there is defective maturation and emigration of the marrow cells the characteristic feature of pernicious anaemia As already noted the highly characteristic megaloblastic proliferation in the marrow (with little emigration of new red cell into the circulation) but also the findings were present in the case not only of active of considerable leucopoietic activity (with nevertheless leucopenia in the circulating blood) The conclusion seems justified that clinically and pathologically this case satisfied all the criteria of pernicious anaemia

The question of whether the lack of response to treatment resulted from the use of an inactive liver preparation or from the case being truly a liver resistant one cannot be definitely answered It can only be said that the particular preparation used has in the hands of other workers given apparently uniformly successful results It is stated that the reticulocytes usually commence to rise within twelve to twenty four hours of the first injection and the maximum reticulocyte response should occur on the sixth or seventh day It would thus appear that in the case under discussion sufficient time was given for the signs of improvement to have appeared had they been going to do so It is regrettable that on humanitarian and on scientific grounds that no opportunity occurred of noting whether or not any other preparation might have had a beneficial effect Had such arisen it would have been strong evidence in favour of the inactivity of the substance first employed As it is it can only be said that the conclusion may or may not be justified that the preparation used was inactive It may be that variations in activity occur even in different samples of the same product as was recently emphasized by Wilkinson[13] in the case of stomach preparations but certainly no case of failure of any sample of this particular product appears to have been reported hitherto

The possibility exists that this may have been a true liver resistant case That such cases occur when orthodox therapy employed is admitted by most observers the figure is 10 per cent of all appears now to be the part of

be hereby unless it is moved or able liver preparation it is functionally active the question introduction of to whether osteo arthritic joints are to be ud Gull and[6] So far as possible movement should be mainc use of it should be more passive than active The dog present of the

body (as according to Sheard et al is strictly speaking necessary) the investigation showed that at any rate a large part of the marrow was highly active Yet the therapy employed should according to the observers already quoted have been quite sufficient to initiate a remission In the absence however of definite proof of the activity of the liver preparation employed it is impossible to decide whether this case was genuinely liver resistant or not

SUMMARY

1 A case is described which clinically and pathologically presented the features of pernicious anaemia

2 It failed to respond to intravenous injections of a liver preparation which has been found by other workers to be highly effective

3 It is suggested either (*a*) that not all samples of this preparation are equally potent or (*b*) that the case is an example of liver resistant pernicious anaemia

THE NOMENCLATURE OF ECLAMPSIA*

BY

BLYTHE SOLOMONS M.D. F.R.C.P.I. F.C.O.G.

MASTER ROTUNDA HOSPITAL

AND

FRANCIS BOURKE L.R.C.P.I.

PATHOLOGIST ROTUNDA HOSPITAL

The text of our paper is the following case

Mrs Mc aged 26 a 3 para had had two normal confinements She attended the prenatal department once in September 1931 but failed to return At that time there was no albumin but the feet were greatly swollen She was admitted to the hospital on October 5th with a history of having had two fits She was given morphine 1/2 grain at 11 30 a.m On examination she was found to be about thirty three weeks pregnant general condition good restless Pulse 70 tension fair blood pressure 122/70 semiconscious Gastric lavage with good results Colonic lavage excellent result Catheter was passed but there was no urine in the bladder At 10 45 p.m the patient was still semiconscious At 12 30 p.m colonic lavage with excellent result Morphine 1/4 grain given on account of restlessness Subcutaneous saline given blood pressure 118/70 Still semiconscious On October 6th general condition fair patient in labour stillborn foetus 4 lb 12 oz delivered spontaneously at ten hours There were signs of consciousness returning and it seemed better colonic lavage achieved a good result but the patient relapsed into a more comatose condition blood pressure 142/70 blood urea 30 mg per cent At 6 15 p.m she had a fit lasting three minutes morphine repeated Patient had further twenty nine fits before 11 40 p.m totalling 31 in all She died at 11 47 p.m

* Read before the Obstetrical Section of the Royal Academy of Medicine in Ireland March 1932

The post mortem report was typical for eclampsia and exemplifies not only the danger of fits in the multipara but also the difficulty of determining whether a patient has eclampsia or not

The post mortem findings were as follows

Right Kidney.—Not enlarged slight cortical congestion and pallor of medullæ pyramids slightly injected

Left Kidney.—Multiple small cortical haemorrhages not enlarged Capsule strips easily Microscopical sections show marked cloudy swelling of the epithelium of the tubules and in many places this has gone on to fatty degeneration There are scattered interstitial haemorrhages the medullary region shows slight increase in the interstitial tissue which suggests an old standing interstitial nephritis

Liver.—Not enlarged normal No haemorrhages Microscopical sections show cloudy swelling of the liver cells There is a good deal of congestion all over

POST MORTEM LESIONS IN THE TYPICAL ECLAMPTIC

Kidneys.— The kidneys are acutely inflamed and closely resemble the kidney in the nephritis of scarlatina They are large soft and congested The capsule strips easily and the glomeruli and tubules are thickly packed with blood and epithelial casts The epithelium of the tubules is in a state of cloudy swelling (Solomons in Tweedy's *Practical Obstetrics*) Symmetrical total necrosis of the cortex Immense firm cloudy yellowish areas of necrosis are infarctions involving more or less completely the whole cortex with thrombosis of intrarenal arterial venous and capillary branches in which Hertzog found hyaline fibrin thrombi (Kaufman vol ii 1910) A glomerulo thrombosis—that is degenerative changes in the vessels and epithelium of the glomeruli is occluded with similar changes of varying intensity in the epithelium of the convoluted tubules There are no signs of inflammatory or atrophic change unless the process has been engrafted upon a pre existing disease In other words the renal lesions are the result not the cause of the process (Hahr)

Liver.—According to Adami In typical cases abundant necrosis in this organ these recall the focal necrosis seen in many infectious and toxic conditions but they may be so extensive as to give the appearance of that wide destruction of the hepatic parenchyma seen in acute yellow atrophy Schmorl quoted by Williams says Irregular shaped reddish or whitish areas scattered through the entire organ and originating near the smaller portal vessels Microscopically they are areas of necrosis involving the periphery of the individual lobules and portal spaces in which blood cells may or may not be present The formation of necrotic areas is due to degenerative changes following thrombotic processes in the smaller portal vessels and these are areas justifying the diagnosis of eclampsia

DEFINITION OF ECLAMPSIA

It will thus be seen that the post mortem results in the case under review and in the typical eclamptic differ so greatly that this case cannot be classed as one of eclampsia and it seems to us that Hahr makes a point when he stresses the fact that the renal lesions are the result not the cause of the toxæmic process Whether the kidney lesion precedes the toxæmic symptoms should in most instances be demonstrated by prenatal care but the irregular attendance by the Rotunda patients makes it difficult to carry this out

We could quote many other cases to exemplify our point but for the present we shall look for a definition We define eclampsia as the occurrence of fits in a pregnant or puerperal woman which would not have occurred if he had not been pregnant Williams does not go so far and defines eclampsia as an acute toxæmia occurring in the pregnant parturient or puerperal woman which is usually accompanied by chronic and tonic convulsions He states that while the convulsions are by far the most striking clinical manifestations eclampsia and coexist the disease in many instances are occasionally met with in which they are absent

We cannot find a definition of eclampsia in the monograph by Stroganoff We consider the necessity for a definition of the highest importance from a statistical point of view and we cannot stand alone if statistics are to be of the least value We must include in our statistics of eclampsia (until it is proven otherwise) those pregnant or puerperal women who die having had fits unless the post mortem results reveal absolutely atypical lesions If the patient does not die she too must for the present be included and if he dies and a necropsy is impossible then she also is grouped as eclampsia Every year since the beginning of the present Mastership there have been cases of doubtful nomenclature and these have been included in the various tables This year however as will be seen in the report there is a separate table for toxæmias of unknown nomenclature

PREVIOUS CASES

The following are some problematical cases

CASE I

1926-27 Report 1 para admitted as eclampsia At 10.30 a.m. baby was delivered with forceps at 12.30 p.m. after the uterus had been emptied of clots rapid collapse set in and the patient became pulseless and unconscious A definite convulsion was reported to have occurred and she soon died It seems possible that this was a death fit and not an eclamptic one but this case is included in the eclamptic statistics

CASE II

1927-28 Report A primigravida aged 42 was admitted at thirty five weeks with a history of having had fits during the last four days before admission She had been semi conscious from the time of the last fit Slightly cyanosed able to protrude her tongue but made no effort to speak No ocular or other paralysis broncho pneumonia in both lungs Blood pressure 118 heart sounds normal reflexes exaggerated slight hypersensitive Consulting physician confirmed diagnosis of pneumonia and suggested that subconscious state was epileptic She remained aphasic Examination of the cerebro spinal fluid showed marked increase of lymphocytes and of globulin no tubercle bacilli found Seen by a neurologist who stated that the patient was possibly suffering from encephalitis but the diagnosis was arguable She died five days after admission All toxæmic tests were negative Blood urea 25 mg. per cent albumin never above a trace

The post mortem findings were *Liver* Pale enlarged fatty small white patches resembling tubercles no haemorrhage or necrosis Microscopically some congestion of intralobular veins The small patches resembling tubercles are small areas of a focal fatty change No evidence of necrosis or haemorrhage *Kidneys* Somewhat enlarged pale slight irregular fibrosis Microscopically congestion and parenchymatous nephritis some area of an early fibrosis and cysts some fatty changes Haemorrhage at the inferior surface of the temporal lobe No tubercles

CASE III

1928-29 Report A 9 para—an atypical eclamptic who was classed as such The kidneys showed evidence of chronic interstitial nephritis The liver was enlarged friable and greasy Sections showed marked congestion especially round the central vein Liver cells clouded and swollen with a good deal of fatty degeneration

There were two cases of [illegible] in report Pohl had fits but he history and his post mortem reports were against eclampsia

In the report for 1929-30 there was a primipara who was admitted as an eclamptic She was reputedly a nurse to have had some sort of fit As the post mortem report showed the typical eclamptic [illegible] she was classified as such if he had not had a fit she could not have been classified

In the present year the report for which has been published there will be found two cases of death (1) a 10 para who was admitted comatose—the post mortem

findings were absolutely atypical (2) the 3 patients described at the beginning of this paper

Enough has been said to draw attention to the fact that the time has come to review our ideas on eclampsia For statistical purposes fits were, in the past considered a necessary accompaniment of eclampsia It should now be decided whether fits are a necessary factor and whether the treatment suitable for the typical eclamptic is suitable also for the atypical—that is for the chronic nephritic There is no doubt that the ordinary eclamptic who has not had a severe cerebral haemorrhage will recover with careful palliative treatment but the woman with nephritis will often fail to do so

TOOTH EXTRACTION AND CHRONIC INFECTIVE ENDOCARDITIS

BY

HERBERT H BROWN MD LRCS
CONSULTING PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN

It is recognized that many chronic diseases especially of the rheumatic type such as arthritis fibrositis neuritis iritis etc are due to the repeated absorption of toxins from a chronic focus of infection with streptococci—generally the *Streptococcus viridans* but sometimes haemolytic streptococci One of the commonest situations for this focal infection is at the apex of a tooth where the toxins are produced under tension and readily absorbed It has become almost the general practice to recommend patients suffering from one of the chronic rheumatic manifestations to have an x-ray examination and if marked apical infection is revealed to have the offending tooth or teeth extracted

DANGER OF LOWERED RESISTANCE

Fortunately even if a large number of teeth are removed at *one sitting* the operation is not generally a very serious matter and recovery is speedy and normal But if for any reason the patient's resistance against streptococcal infection is low there may be very serious danger As Sir William Willcox[1] has pointed out

> The resistance of a person to a dental infection may be broken down by the constant doses of the blood stream with toxic products from the focus of infection A condition of constitution then results I have on several occasions seen fatal septicaemia and malignant endocarditis follow extraction of infected teeth in a patient in poor health with a low immunity

It is to this grave danger that I especially wish to draw attention It may and certainly does, happen that chronic infective endocarditis comes on without any obvious cause although in these cases the same germ generally the *Streptococcus viridans* which is present in the blood may be cultured from the apex of an infected tooth This suggests that the tooth was the primary focus of infection in a patient whose blood shows an abnormal deficiency in bactericidal powers against this organism But blood infection is more likely to occur in a patient with a very low degree of immunity if blood and lymph channels are opened up by the trauma of tooth extraction especially if the extraction is a difficult one requiring more force than usual

In recent years local anaesthesia by infiltration of the gum and tooth socket with an anaesthetic such as novocain has been very widely practised Where there is obvious septic infection of the gums a local anaesthetic is not often given but in apical infection only revealed by x-ray examination it is quite usual for extraction to be performed under *local anaesthesia* I think there can be no doubt that forcing a fluid under *considerable tension* into the *comparatively* rigid and resisting tissues of the *gum and periodontal* membranes must tend to carry any *germs which may be* present in these tissue into the lymphatics, *and so to the blood* stream with a danger *if the blood should* happen to have no bactericidal power against the infecting organism of starting a serious and fatal blood infection such as subacute infective endocarditis Two cases of this disease following tooth extraction under local anaesthesia are recorded in the *British Medical Journal* (July 1931) by Dr L Abrahamson In each case there was pre existing valvular disease and in both local anaesthesia was used

I had the opportunity of seeing not long ago another case in which chronic infective endocarditis followed immediately upon extraction of a tooth

ILLUSTRATIVE CASE

The patient a lady *of about* 50 was in a poor state of health and had been advised to have her *teeth examined* The radiologist found evidence of alveolar absorption in most of the teeth but especially in three of them He advised that owing to the state of her health little should be *done at the moment* but recommended that one of them which showed the greatest evidence of damage should be extracted This was done on October 26th 1929 but I have not been able to ascertain whether local anaesthesia was employed *On the following day* her temperature rose slightly and continued a subfebrile course *from* 99° to 100° or 101° I *during* the remainder of her illness

Haemolytic streptococci were cultured from the tooth socket but were not found in the blood The leucocyte count was 8 000 polymorphs 71 per cent and the polynuclear count showed a marked shift to the left Streptococci were also cultured in the patient's blood which had no bactericidal *effect upon them* The pathologist concluded that it was probable that there was a low grade blood infection although no growth had been obtained from the blood

Ten days later she was visited by a London consultant who reported that heart and lungs were sound and gave a good prognosis as to recovery A month later another blood examination and culture was made leucocytosis had now increased to 13 000 polymorphs 77 per cent *but still no* culture was *obtained from* the blood The consultant who *had been kept informed* of the progress of the case expressed his belief that he was suffering from a low grade type of *septicaemia* from a focal infection in *connexion* with the teeth and strongly urged the advisability of the extraction of more teeth as he believed that she would not improve until the focus had been removed Three teeth were accordingly extracted *between* December 18th and December 28th *under local anaesthesia*

The temperature rose somewhat after the first extraction and her general condition became rapidly worse I saw her for the first time on January 4th She was then in a very serious condition obviously suffering from endocarditis and myocardial infection She died on January 10th 1930

The mode of onset of the symptoms and the course of the disease clearly indicate a blood infection with subacute endocarditis originating from the first tooth extraction and very much aggravated by the three subsequent extractions under local infiltration, which introduced a larger number of streptococci into the blood stream The febrile condition was not due to repeated doses of toxin *from* an infected focus but to the elaboration of toxin in the blood from the blood infection with streptococci Removal of more teeth materially aggravated the infection adding fuel to the fire

COMMENTARY

The danger of extracting teeth with apical streptococcal infection is a real one as these cases show and I feel convinced that the danger is increased if local anaesthesia by infiltration of the gum is made use of

Unfortunately it is not at present feasible to estimate the patient's blood resistance to the infecting organism unless a culture can be made and tested against the

blood To do this a tooth must be extracted But it would be wise precaution especially in the case of an individual already suffering from valvular disease or one who may seem for other reasons to be liable to have a weak resistance to extract *one tooth* only in the first instance under a general anæsthetic such as nitrous oxide to make a culture from the tooth and to test the patient's blood for bactericidal power against it If the blood has no bactericidal power an attempt may be made to improve it by graduated doses of vaccine beginning with very small doses before any more teeth are removed In any case of this kind a general anæsthetic is indicated

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

HÆMATOMA OF THE GASTRO COLIC OMENTUM

This is a case of such rarity that I am prompted to submit it for publication

A married woman aged 31 attended the out patient department Soho Hospital for Women on June 16th 1931 complaining of an abdominal swelling which she had noticed for fourteen days and which at times disappeared During the previous two days it had increased in size and had become tender In the preceding week vomiting had occurred twice and was accompanied by severe pain in the region of the swelling She noticed that on walking there was a dull aching sensation around the umbilicus Both micturition and menstruation were regular The patient had four children and her confinements had been normal

On examination there was found to the left of the mid line and just above the umbilicus a circumscribed dull tender mass about the size of a small orange It was freely movable Examination of the pelvis cardio vascular respiratory and urinary systems revealed nothing abnormal Radiograms of the kidneys demonstrated no displacement of these organs

Laparotomy was performed on July 7th A purple coloured lobulated mass was found lying in the gastro colic omentum Inferiorly it was attached to the upper and anterior aspect of the middle of the transverse colon while superiorly it was found adherent to the greater curvature of the stomach The mass was easily liberated from the colon but was firmly fixed to the wall of the stomach During the manipulations the capsule ruptured The fluid discharged was tarry and glutinous bearing a marked similarity to the contents of a chocolate cyst of the ovary The greater portion of the mass was removed but the upper pole was so firmly fixed to the stomach that it was deemed wise to leave it Into this remaining loculation a small rubber drainage tube was passed The rest of the abdominal viscera were examined and appeared to be normal The drainage tube was removed after twenty four hours Convalescence was uninterrupted and the patient left the hospital three weeks after the operation

The pathological report records the presence of a mass of blood clot with a capsule of fibrous tissue no omental tissue was to be seen

The literature on the subject is scanty Louis Timbal[1] published a monograph in which he described two cases of hæmatoma of the great omentum both patients dying There are three varieties of blood cysts (1) a true serous cyst into which bleeding occurs (2) a primary encysted hæmatoma of the mesentery or omentum due to a rupture of an arteriole (3) a hæmorrhage into the general peritoneal cavity which becomes secondarily encysted In the mesentery or omentum Trauma is a common factor in the aetiology It is interesting to note that there was no history of injury in this case Only by pathological examination can the types be differentiated In the case described there was merely a mass of blood clot surrounded by fibrous tissue The hæmorrhage had not taken place into a true and preformed space since no serous covering could be identified in the microscopical section

I should like to express my gratitude to Mr H Sidney Lonsdale for allowing me to publish this case

CLINICAL AND SCIENTIFIC PROCEEDINGS

SOUTH EASTERN COUNTIES DIVISION

Specific Therapy of Puerperal Fever Erysipelas and Scarlet Fever

At a meeting of the South Eastern Counties Division of the Edinburgh Branch held on March 16th with Dr MARSHALL in the chair an address was delivered by Dr J W BENSON medical superintendent of the City Hospital Edinburgh on the specific therapy of puerperal fever erysipelas and scarlet fever

Dr Benson considered that these diseases were all manifestations of infection by haemolytic streptococci but there were essential differences in the disease processes In scarlet fever the streptococcus remained in the majority of cases localized in the throat the systemic disturbance—as evidenced by rash pyrexia headache and vomiting—being due to the absorption of soluble exotoxins In erysipelas the infecting organisms were situated in the deeper layers of the skin where was set up the inflammatory process which showed the characteristic tendency to spread Constitutional disturbance pointed to the absorption of toxin the fact that erysipelas characterized by severe systemic disturbance not infrequently occurred in Dick negative individuals suggested that the toxaemia was due to an endotoxin In puerperal infection a new problem appeared—namely the invasive power of the haemolytic streptococcus A serum to be effective required not only to be able to neutralize toxins produced by infecting organisms but to destroy germs it must be bactericidal as well as antitoxic The facts that the exotoxins produced by different strains of *Streptococcus haemolyticus* seemed to have no qualitative difference and the majority of them were neutralized by a single antitoxin had an important bearing on the serotherapy of streptococcal infections in general The therapeutic serums could be divided broadly into two groups antitoxic and antibacterial Antitoxic serum aimed at the direct neutralization of bacterial exotoxins and proved reliable in practice The acute toxaemia shown in diphtheria tetanus and scarlet fever was of only a few days duration and the injection of an adequate amount of neutralizing serum would enable a patient to pass the acute stage On the other hand antibacterial serums had proved disappointing It was necessary for the actual destruction of invading germs and the neutralization of endotoxins Here adequate dosage was essential and since the bacteraemia which by protracted the injection might have to be continued over a comparatively long period The following were the therapeutic serums again Localized streptococcal infections were now available scarlet fever serum erysipelas antitoxic serum and puerperal fever antitoxic serum The essential difference between these polyvalent serums and the polyvalent antistreptococcal preparations

they were rapidly displacing was their high antitoxic content. Since the exotoxins produced by the various strains of haemolytic streptococci were regarded as being qualitatively identical, what fever antitoxin might be expected to neutralize the exotoxins in all three infections is a matter of fact if administration was regarded as sound practice.

In serum therapy the three important factors were early administration, adequate dosage, and the route of injection. It must commence within seventy-two hours of the onset of illness—the earlier the better. No hard and fast rules regarding dosage could be laid down, but broadly speaking serum treatment should be continued till definite improvement ensued—daily for a week or even longer. The intravenous route permitted the serum to exert an immediate effect. It was contraindicated in small children, asthmatics, and individuals who gave a history of previous serum treatment, in these the intramuscular route should always be adopted. Owing to the delay in absorption the subcutaneous injection of serum had nothing to commend it. Where untoward symptoms occurred in the course of intravenous administration it was necessary to stop, and before withdrawing the needle to inject 0·5 to 1 c.cm. of adrenaline. In cases where there was reason to suspect increased sensitivity to serum it was important to desensitize by giving initial subcutaneous injections of 0·25 c.cm. serum, followed by 0·5 c.cm. and 1 c.cm. at hourly intervals. Should no untoward symptom follow these initial injections a full therapeutic dose could be introduced intramuscularly one hour later. In serum sickness, where an urticarial rash was profuse and the discomfort correspondingly great, 5 to 10 minims of adrenaline subcutaneously or 0·5 to 1 gram of ephedrine administered occasionally by the mouth acted like a charm. In scarlet fever little could be expected from serum administration after the fourth day of illness, and in septic scarlet fever, where the characteristic feature was the invasive power of the haemolytic streptococcus, it had proved disappointing. Complications such as otitis media, rhinitis, and suppurative adenitis did arise in spite of serum treatment. In the City Hospital serum treatment was reserved for the more severe cases showing such symptoms as obvious toxic appearance, severe prostration, persistent vomiting, or diarrhœa, delirium, a very rapid and soft pulse, a temperature of 101° F. or above, and severe faucial inflammation. Serum was also given where a mild scarlatinal infection was superimposed on a previous illness to debilitated children, and to return cases as a matter of policy. In attacks of moderate severity 30 c.cm. of serum was injected intramuscularly; in most patients the injection did not require to be repeated. Where the toxæmia was severe it was advisable to inject intramuscularly 30 c.cm. followed by 30 c.cm. intravenously one hour later, the latter injection could with advantage be combined with half a pint of 10 per cent. glucose saline solution. Injections should be continued at twelve hourly intervals until the symptoms were relieved.

Puerperal infection differed essentially from scarlet fever in that the haemolytic streptococcus tended to invade the blood stream, whereas in scarlet fever a toxæmia was present; it was consequently not reasonable to expect a purely antitoxic serum to be equally efficacious. Clinical evidence regarding the value of puerperal antitoxic serum or scarlet fever antitoxic serum was conflicting. Experience in the City Hospital had left the speaker with the feeling that an effective therapeutic serum against haemolytic streptococcal septicæmia had yet to be produced, although it was only fair to add that most of his cases did not receive serum before the third or fourth day of illness. In cases of erysipelas both erysipelas antitoxin and scarlet fever antitoxin had been freely administered to some 200 cases of erysipelas in the wards of the City Hospital during the past five years. The results were not encouraging; the spread of local inflammatory process was not checked, but in some instances there had been a definite alleviation of systemic symptoms such as headache, delirium, pyrexia, and malaise. The speaker suggested, however, that where the constitutional disturbance was severe, more particularly if the patient was at the extreme of life, 40 c.cm. of erysipelas or scarlet fever antitoxin might be injected before the third day of illness, and be repeated if necessary on three successive days. In infants a daily intramuscular injection of 10 c.cm. would be adequate.

In conclusion, Dr. Benson expressed the view that apart from scarlet fever no particular advance had been made in the serotherapy of haemolytic streptococcal infections. Even in scarlet fever the serum was almost purely antitoxic, and thus too much could not be expected from it in the septic type of case. In puerperal septicæmia and erysipelas, in addition to the soluble exotoxin, the invasive power of the streptococcus and its endotoxins had to be borne in mind. For a serum to be effective against these streptococcal infections it must contain, besides antitoxin, effective antibacterial substances, and the speaker maintained that such a serum had not yet been produced.

Reports of Societies

MICROSCOPY OF FILTERABLE VIRUSES

The meeting of the Royal Microscopical Society held at the British Medical Association House on April 20th was for the special consideration of the microscopy of filterable viruses. The discussion was opened by Mr. CONRAD BECK, the president, who described the technique of dark ground illumination and the use of ultra-violet light. Photography with ultra-violet light he said was as certain and reliable as ordinary photography, and in some cases the resolution appeared to be better than theory and practice hitherto had suggested. This might be due to the well-known property of a photograph of showing in certain instances what the eye could not see. Essentially the question was one of contrast between the object or elements in its structure and the background. Where stain was not desirable or as in the case of living organisms could not be adopted, the question of visibility required careful attention. The combination of ultra-violet light with dark ground illumination had at least doubled the power of the microscope.

Mr. J. E. BARNARD said that during the last three years he had attended two discussions on the subject of filterable viruses—one held at the Royal Society in 1929 (*British Medical Journal*, March 9th and 23rd, 1929) and the other at the British Association last year (ibid., October 3rd, 1931). At the latter he noticed a marked change in the outlook of workers in this field. It seemed to have become pretty clear that a virus was probably a small organism differing chiefly in size—although it might have other physical differences—from the larger and well-known bacteria. If that was the case it was obvious that this subject came definitely within the province of a microscopical society. He laid down three propositions: (1) that the observation of small organisms could best be effected with living material (advantage could then be taken of morphological and physical differences which were obliterated in a post-mortem examination); (2) that to achieve the necessary microscopical resolution visibility must be secured, and the record of the elements of structure lying in one plane and separated one from another by distances equal to or greater than

the resolution limits was best obtained by a dark ground illumination (3) that the necessary combination of visibility with the resolving power was only to be arrived at by the use of light of short wavelength the wavelength required depending on the size of the organism which was being studied Mr Barnard then showed a few photographs of the organism of vaccinia which he had selected for the reason that its size was in one dimension at least always below the resolution limits of microscopy with visible light When the organism elongated lightly as it did before subdivision then it just came within the resolution limit Here therefore one had an organism of two dimensions—one within the limits of resolution of the microscope with visible light and the other outside those limits

Professor J C G Ledingham feared that the microscopy of filterable viruses was at present practically restricted to cell inclusions and elementary bodies So far as cell inclusions were concerned there was no doubt that their presence was almost valuable guide to the existence of particular virus infections and there was no evidence at all that the cell inclusions could be reproduced by any artificial experimental means On the other hand with two or three exceptions no precise knowledge of the composition of these cell inclusions was forthcoming With regard to elementary bodies in relation to vaccinia fowl pox and so forth there were now good grounds for knowing that they did represent the infective agent of the virus During the last five months he had been studying the filterable virus so called of bovine pleuropneumonia It was always said that this was the only virus capable of cultivation in an artificial medium But was it a virus in the ordinary accepted sense? His observations went to show that probably it should not be considered a virus at all More likely it was a bacterium or fungus possessing elements so small as to be capable of passing through the lower grade of filters He traced the history of the work on this virus and described its extraordinary polymorphism The organism appeared to be of a highly plastic nature Some workers had emphasized the difficulty of studying agar preparations of the virus owing to its capacity for burying under the agar but it was a very easy thing to take a slide press it down with finger and thumb over the growths for half a minute bring it up and stain He had had no difficulty in getting quite excellent stained preparations of the various stages Quite provisionally he was inclined to consider the organism of pleuropneumonia not as a virus but as an organism with fungal characteristics

Dr S P Bedson said that for many years now elementary bodies had been stained and studied in a number of filterable viruses and it seemed to him that one of the chief problems which confronted workers at present was to find out whether the bodies were the virus or not In attempting to solve this question with one filterable virus he had relied on purely conventional methods The methods followed by Mr Barnard were of course of the very greatest value but they were not at the disposal of everybody and possibly in the hands of those to expert might lead to error Conventional methods which had been employed in the laboratory for years now could be used in the solution of this problem The elementary bodies of psittacosis were quite definite structures By fractional centrifugation and washing he had found a certain deposit consisting of these elementary bodies and that a culture was produced by this body He had however discovered that they could be partially adsorbed out of an antityphus [illegible] and were recovered by extraction and again [illegible] from a vaccinal lymph which he had [illegible] charged He thought it could be deduced that the minute elementary bodies seen in the organism were the virus Although the method might not be applicable to all filterable viruses it could be applied to a number of them and should make it possible to determine whether the bodies seen under the microscope were the virus

Dr C C Hurst illustrated virus disease of the potato which took on he said various symptomatic and clinical forms specifically differing according to the variety of the vegetable and its tissues Four specific virus entities had been demonstrated

Professor J McIntosh asked for a definition of a filter passing virus He thought the differentiation between a visible bacterium and a filter passer was purely artificial in that it depended on the resolution limits of the microscope That was not a sufficient criterion to distinguish between two living elements It was quite possible that many of the filter passing viruses were really small bacteria in every way comparable to the visible microorganisms Working on this hypothesis there was a tendency to apply methods used in the case of the visible organisms for the differentiation and identification of the filter passers With the ordinary organism there were available microscopical examination and experimental and cultural methods Speaking purely from the practical aspect he was soon convinced that for the recognition of filter passing viruses and their separation into a definite entity these methods could not be applied with the same ease For example in the case of ultramicroscopic viruses reliance had been placed almost solely on the pathogenic effects on animals for the differentiation of the virus The microscope was used as a controlling element in close association with these animal experiments However useful in future direct microscopic demonstration of these viruses might be it was inconceivable that by this means alone the virus could be identified One did not at present make any attempt to identify and put in its proper group a bacterium solely by the use of the microscope although of course it was necessary to have the microscopical method as a control He showed some preparations of inclusion bodies which were of interest Professor Ledingham had said that only in the case of fowl pox and one or two others had it been possible to demonstrate bodies inside the inclusion but he had a section showing the Paschen body the inclusion body in vaccinia in the epithelium of the cornea of the rabbit which when stained showed the same definite granular arrangement as was found in the case of fowl pox

Captain S R Douglas discussed methods of staining The methods usually employed in staining virus bodies had he said been practically of one kind and had the disadvantage of piling up the stain on the outside of the organism Lately two new methods had been evolved In one of them Dr Laidlaw's acid stain was used which gave a good picture at times of a red-brown inclusion body The other method rather neglected in bacteriology and other studies was to float the organism in the stain and examine the wet preparation

Dr W J Elford dealt with an aspect of microscopical technique which in this particular problem assumed more than usual importance—namely the preliminary investigation in the preparation of the object The pathogenic agents the filterable viruses had so far been found unable to cultivate on inanimate artificial media [illegible] from living cells It had been necessary to examine [illegible] through series of graded collodion membranes The filtration of the virus could not take place in a single membrane but in a series of membranes each of different porosity He gave a list of those with which he had experimental dilutions in which the filtration had been completed varying from 0.125 to 0.175 μ infectious

ectromelia 0·10 to 0·15 μ herpes 0·10 to 0·15 μ foot and mouth disease 8 to 12 μμ

Dr I HINDLE said that to his mind there was evidence of a variety of structures associated together which possibly had no direct connexion He was in complete agreement with Professor McIntosh From a practical point of view he thought the use of the microscope distinctly limited In the case of larger organisms such as bacteria very few could be identified under the microscope which was merely a check on experimental and cultural methods In the case of viruses it would probably be found that simpler methods would have much greater importance than a direct examination of infected material The record of direct examinations of infected material was unfortunate A whole host of different bodies had been described as the infective agent in disease Therefore while Mr Barnard's methods were very useful he thought the future in the study of virus disease would lie in the development of cultural methods and the biological identification of the different infective agents

Mr J K JOUSSO spoke from the physical point of view The use of short wave lengths was of great value on account of the increase of resolving power obtained and also the elective adsorption of the specimens made it possible for virus qualitative tests to be made

Dr G M FINDLAY said that one of the most important things in the advance of microscopy by ultra violet light was the separation from colloidal particles with which the organisms were so closely mixed The results of differential centrifugation and filtration had been already mentioned There were two other methods One was that of adsorption of the tissue or enzyme with some substance such as kaolin the kaolin was then washed and subsequently the tissue extracted therefrom In some experiments (in which he had taken part) on the virus of vaccinia it was found comparatively easy to adsorb the virus on to kaolin but as in the case of enzymes the various kaolins differed in the ease with which they adsorbed the vaccinia virus The suspension could usefully be treated with a dilute solution of lead acetate previously afterwards the kaolin having been washed the virus could be removed by treating the kaolin—preferably with dilute ammonium phosphate In the fine granular deposit obtained it was possible by staining methods to see very minute granules which when inoculated into the rabbit were highly infective The other technique was that of micro dissection as described by Professor Chambers This was one which might be applied to many investigations of virus diseases It had now been shown that the intranuclear inclusion bodies were present in the living cell Their nature was at the moment unknown but it seemed probable that they did contain the actual virus because they could be observed to grow in the nucleoplasm and by the technique of micro dissection they might be sorted out and further studied under the microscope He believed there was no distinct line of demarcation between actual bacteria and the ultra microscopic viruses

PUERPERAL FEVER AND PYREXIA

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on April 22nd with Professor MAJOR GREENWOOD in the chair Dr A S M MACGREGOR medical officer of health for Glasgow read a paper on Puerperal fever and pyrexia

Dr Macgregor said that his paper was an attempt to assess the problem to be dealt with in a big industrial city At an earlier discussion in 1924 in which the Section with other bodies had joined the question of paramount importance was the notification of puerperal pyrexia the provision of adequate hospital facilities and the rendering of assistance to the general practitioner All these administrative ideals had now been realized but to judge from the stationary or even rising death rate the efforts of local authorities to control puerperal sepsis had not met with success The more the actual facts were disclosed the higher became the rates of incidence and mortality Special studies had been made in Glasgow of the volume of infection disclosed by the notification of puerperal fever and pyrexia The number of cases notified last year was 891 and in half the cases the notification of pyrexia meant puerperal sepsis This correction having been made the incidence of puerperal sepsis was just over 27 per 1 000 births The maternal deaths per 1 000 births in Glasgow had risen from 6·9 in 1921 to 8·57 last year Previous to the beginning of the century there had been a fair correspondence between England and Scotland in respect of maternal mortality and puerperal sepsis but since then the figures showed a wide divergence the higher figures relating to Scotland No great significance was to be attached to the comparison of the mere figures as the methods of classification in the two countries were different but as there appeared to have been no change in practice for many years the general trend might be compared and in recent years it had been upward in both countries In Glasgow the number of admissions to puerperal wards had increased from 119 in 1913 to 405 in 1931 with this increase in hospitalization had gone of course a decrease in case mortality Of puerperal fever patients 93 per cent were now either admitted to the special wards of the isolation hospitals or were treated in the maternity hospitals where the case occurred but in spite of the ample provision of hospital beds little impression appeared to have been made upon puerperal mortality The mortality rate from puerperal sepsis (3·1 in 1931) had not sensibly diminished This maintenance of the high rate was probably due to the continued occurrence of the severe septicæmic type of case and to abortion sepsis which accounted for about 22 per cent of the total fatalities due to septic infection The mortality rate from puerperal sepsis being apparently so intractable it was necessary to examine the results of administrative procedure Here Dr Macgregor showed an analysis prepared by Dr Margaret Thomas of 800 consecutive hospital admissions with 122 deaths Miscarriage and abortion accounted for 24 per cent of the admissions and 20 per cent of the deaths The cases had been classified clinically into four groups, of which the fourth representing those associated with severe blood infection provided 74 per cent of the total deaths although the cases in this group as compared with those in other groups did not appear to have been unduly delayed in admission to hospital It was evident that in all the groups there was undue delay in many cases (though an improvement had taken place in this respect compared with former years) and prognosis was adversely affected The policy of hospital treatment was now having a fair trial though it was handicapped by the presence of a virulent form of infection in which post operative sepsis took a prominent and increasing share It might be that infections with the hæmolytic streptococcus like infections with the pneumococcus tended to be more severe in the northerly parts of the kingdom There was no definite evidence to postulate a carrier The tenement system in Glasgow might be regarded as favouring the incidence and severity of puerperal sepsis by increasing the danger of carrier infections in congested areas but there was no definite evidence of such association and the incidence of puerperal sepsis occurred fairly equally throughout the city irrespective of the type of residence In a local investigation of 200 consecutive deaths from puerperal sepsis it was found very difficult to assess the attendant

circumstances when the patient was presumed to have become infected but the inquiry corroborated the view that labours in which some form of intervention had taken place were more liable to end in sepsis Of the 200 cases of death from puerperal sepsis 90 were difficult labours while forceps had been applied in 48 Too great significance however was not to be attached to the latter figures as obviously much depended upon the extent to which a practitioner was accustomed to use forceps in his ordinary practice

Dr REDINGTON HOBBS said that though the puerperal sepsis regulations by including puerperal pyrexia had brought many more cases into hospital the standard of morbidity left much to be desired and allowed a large leakage of cases to take place But until a serum or vaccine could be invented which killed the organisms at once reliance must be placed on the other signs of inflammation and if possible prophylactic measures be instituted Directly a woman came to the consulting room he thought it as well to see whether she had an erosion and any leucorrhoea Again most cases which showed *B coli* in the urine had a similar genital infection

Sir W DALRYMPLE CHAMPNEYS referred to the difficulties which faced those who framed the puerperal pyrexia regulations It was impossible to create a rule which would bring into notification all and only those cases which should be notified His feeling was that the regulations had done an enormous amount of good and but for them this fine piece of clinical and statistical research at Glasgow would probably not have been undertaken Dr JANE TURNBULL said that for Dr Macgregor to have got 60 per cent of the patients into hospital within three days of onset was an excellent result In investigating reports of maternal deaths a disturbing factor had been the lateness of admission

Dr G CLARK TROTTER said that general practitioners in good neighbourhoods and with excellent records for their maternity cases were sometimes appalled on the occurrence of puerperal pyrexia suspected to be sepsis But it was possible that just as children in better class districts did not have the acquired immunity to infectious diseases possessed by children in poor and overcrowded districts so women attended in better class practices might be more susceptible Dr D SIGF SUTHERLAND said that in Manchester considerable attention had been paid to blood infection Blood examinations were made immediately a case was admitted to hospital and quite a large number of patients showed a minor infection This could be controlled by Colebrook's method of giving arsenical drugs All the cases were centralized in the isolation hospital and the death rate last year was 8 per cent Antito in serum had been given up it was found less effective than arsenical drugs associated with glycerin and iodine irrigation Dr A S MONCKTON COPEMAN mentioned the use of oil of turpentine given externally and internally

The PRESIDENT remarked that he could not discover the relevance of most of the statements in the discussion Dr Macgregor's difficulty was that 95 per cent of the cases that occurred in his city and over 95 per cent of the deaths actually occurred under the most favourable conditions In spite of prompt and effective administrative measures the patients still died and what Dr Macgregor wanted to know was whether this apparently stationary or even increasing mortality was a true phenomenon It might be that there were subtle sociological changes which meant that the exposed to risk had a rather different connotation

Dr MACGREGOR in reply said that he was not prepared to admit that the figures for Glasgow were comparatively high until he knew that the same effort was made elsewhere to find out and classify the causes of death

INFECTION IN THE DORMITORY

The Section of Epidemiology and the Section for the Study of Disease in Children under the chairmanship of Sir HENRY GALVIN had a combined discussion at the Royal Society of Medicine on April 19th on infection in the dormitory

Dr J ALISON GLOVER in opening said that many authorities from Pringle onwards and including the Royal Commissions of 1857 and 1861 had emphasized the importance of space in preventing infection in sleeping quarters Infection in the dormitory was but one aspect of infection in the boarding school but it was very important in most schools the exceptions being a very few boys schools where dormitories were adequately spaced and most girls schools where the pupils slept in cubicles of proper size The part played by the dormitory was shown by the fact that the incidence of infections was greater in boarders than in day boys He mentioned one small public school where during an epidemic of scarlet fever the 132 senior boarders showed an attack rate of 32 per cent while of the seventy five day boys only three were affected The variation of incidence in different dormitories was often significant A small outbreak of scarlet fever due to a heterogeneous strain of haemolytic streptococcus happened in a school in which the hygienic conditions were exceptionally good There were eight cases in the whole school of 475 four of these being in one dormitory in which twenty nine boys slept Investigation showed that this dormitory was one of two which had slight overcrowding of beds Bacteriological examination eighteen days after the last case revealed a still considerable carrier rate Three of the subsequent cases occurred in the other dormitory which was slightly overcrowded Bed charts of dormitories on which the dates of onset had been noted frequently showed a grouping so suggestive that coincidence seemed unlikely When the bacteriological results of simple throat swabbings in a dormitory were charted the groupings of carriers often pointed clearly to bed to bed infection The conditions in dormitories which favoured a rapid and easy transmission of infection were proximity of beds deficient and not cross ventilation insufficient floor space dead space in ceiling and dead corners More than two rows of beds were to be deprecated The minimum suggested by the Board of Education for dormitories should be strictly observed—namely at least 3 feet between beds floor space of not less than 65 square feet per bed and cubic space of 700 cubic feet with ventilation adequate and through by arranging the windows on opposite sides of the room

Surgeon Captain S F DUDLEY after making the assumption that where people slept in congested dormitories a large proportion of the infectious morbidity was contracted in bed contrasted the former conditions on the training ship *Impregnable* with the conditions at Shotley also a naval training establishment On the *Impregnable* the lads slept in hammocks which touched one another At Shotley the sleeping conditions were less dense There was little difference in the attack rates for the most infectious types of disease the figures being 154 in the *Impregnable* and 147 at Shotley per thousand per annum The prevalence of more serious infections and complications was however higher in the establishment with the denser night environment—for example for pneumonia thirteen and six per thousand respectively for rheumatic fever nineteen and ten and for respiratory disease (a heterogeneous classification) 401 and 252 This raised the question whether an improvement in sleeping quarters too small to check total morbidity might not limit the clinical severity and the number of complications It was Captain Dudley's belief that the organisms of the commoner infections could easily traverse 3 or 4 feet during

the nine hour night. With beds arranged in pairs each pair being 9 feet from the next although each member of the pair ran a greater risk of infection running through the whole dormitory. Certain observations suggested that there was not likely to be infection running through the whole dormitory. Certain observations suggested that institutional morbidity might be decreased by using new comers relatively more space than older residents and by grouping beds in dormitories instead of having them equidistant. A speculation arose from some phenomena observed when people were closely aggregated at night—namely, as to whether parasites were able to acquire new pathological attributes in densely packed dormitories and cause outbreaks of disease outside them. I shall only theorize. Recently some authors had attributed more importance to the spread of disease by insanitary methods of washing up eating utensils and the question is worth serious attention as to whether droplets or dish water was the more common vehicle of infection.

Dr. R. I. Sutton (Rugby) said that the average per head in the dormitories at Rugby was 66 square feet of the capacity 784 cubic feet. The floor space in the studies was 114 square feet and the capacity 265 cubic feet. The studies which lacked the cross ventilation of the dormitories might be a greater source of danger than the latter. The boys also came into close contact in the dining hall and in the chapel where they sat shoulder to shoulder while in the classrooms they were separated only by about 3 feet. Influenza was one of the chief problems of the school medical officer because it was completely different from the common infections in that one attack conferred immunity only of short duration. Most of the epidemic at school occurred during the Lent term and the most useful preventive measure against influenza would be to ensure that during the Christmas holidays plenty of outdoor exercise was taken with the minimum of indulgence in parties. He was strongly opposed to routine vaccination for influenza. He also pointed out that the nurse might be a preventable carrier of infection.

Dr. W. H. Barnes (Downside School, Bath) showed a number of charts illustrating dormitory spread. He said that the dormitory was the main location of the spread of disease in semi-isolated communities. The day time contacts of the boys were not blameless but were of minor importance and in any case beyond easy control. The dormitory if it was to survive must be hygienically sick rooms irrespective of its symmetry or attractiveness. His experience of secondary infections in spread and grouped beds appeared to be more essential than perfect ventilation important though that was. His own ideal was a separate room for night use only.

Dr. Dorothea Taylor (Bedales School, Petersfield) said that Bedales was a co-education school and there were six or eight in a dormitory on each side. Her impression was that sometimes the dormitories were a source of infection with influenza and measles. With regard to sex incidence there was a strong feeling that the boys were all much more frequently than the girls and that was certainly the view of the matrons on both the girls' and the boys' sides but examination of the statistics showed that the incidence was exactly the same for boys as for girls.

Dr. I. R. Lemerle (Haileybury) said that the spread of infectious diseases in schools depended on the type of school. He described a hostel school in which the boys slept in large dormitories forty-eight per dormitory. In this school the same boys were grouped together in sleeping rooms day rooms classes and to a large extent at games. He believed that spread took place far more readily in the house rooms than in the dormitories. A low partition in the dormitory would very largely prevent the transmission of droplet infection. He gave some figures collected during the nineteen epidemics of the common exanthemata which showed that 32 per cent. had been traced to the dormitory 28 per cent. to the house or form room and 16 per cent. to the house or form while in 21 per cent. the origin was unknown.

Dr. A. L. Sutcliffe (Malvern) made a plea that as practically 100 per cent. of the community was bound to get measles the enormous amount of precaution taken at preparatory schools should be considered a mistake. He also said that in his experience serious streptococcal complications occurred chiefly in the fat and flabby type of girl of 15 or 16.

Dr. P. M. May (Royal Hospital School, Greenwich) confessed his wonder that spread in schools was not more marked. In his school of 900 boys last year there were only four isolated cases of mumps and yet the boys were all in contact with one another. At the same time the class of children with whom he had to deal was that which had got salted in early life this furnished a happy immunity from a great number of infections which would otherwise occur.

Dr. Alice Sandilands Clow (Cheltenham) said that she had made inquiries relating to thirty-three separate educational establishments in Cheltenham and although careful records of sickness were kept there were no notes of spread of infection among occupants in the same dormitory. The general opinion was that the spread of infection could not as a rule be traced to dormitories. One of the features of the construction in the Cheltenham colleges was the loftiness of the rooms which were 11 to 14 feet in height. Under such conditions cases might occur and yet if the case was removed at once there was no transmission of the infection to the other occupants of the room. To her mind colds and influenza were the most serious infections in schools at the present day in that collectively they caused the greatest waste of time and one attack conferred no immunity. Mumps and measles might almost be regarded as a part of general education. She had questioned whether elaborate arrangements to prevent dormitory spread were necessary because she had observed that especially in the chilly season the children generally slept with their heads down under the bedclothes. She believed that infection was most commonly transmitted in overheated and stuffy day rooms and living rooms.

Dr. E. W. Goodall pointed out that sex itself was a differentiating factor in connexion with the mortality and morbidity of certain infectious diseases. For example there was a higher mortality among girls from whooping cough and among boys from measles. He spoke of the large number of factors which had to be considered in addition to the structures of dormitories in assessing the spread of infection in institutions.

Dr. E. P. Poulton mentioned a preventive measure against droplet infection—namely, the massive application of a simple inert substance to the nasal mucous membranes. Spray was relatively ineffective for this purpose but an application of liquid paraffin and white vaseline perhaps with menthol had proved very efficacious in stopping respiratory infections in the early stages. The preparation which he had introduced had been placed on the market by British Drug Houses. Dr. W. R. P. Collis also spoke of the efficacy of this method.

Sir Henry Gauvain in closing the discussion said that the chief thing which every speaker had directly or indirectly emphasized was abundance of fresh air for the dilution of infection. In the light of experience gained during a quarter of a century at Alton a new hospital

was being built there in a special way so as to take the fullest possible advantage of the open air The wards were so arranged that an infinite amount of air would be available It was not a question of having 3 feet between beds but of having the whole air of Hampshire He also mentioned the importance of sterilizing the utensils used by the children and added that discomfort from cold was not at all necessary in open air treatment and that the solution of providing warmth was to be found in the panel system of heating

THE ORIGIN OF TUMOURS

The first medical meeting of the Harley Medical Society was held on the premises of the London Clinic and Nursing Home Dr H MORELAND MCCREA who occupied the chair during the first part of the proceedings said that it was with the object of keeping alive scientific ideas in their own circle that the society had been formed The DUKE OF ATHOLL on behalf of the London Clinic and Nursing Home expressed his sense of privilege in being present to hear the discussion which would ensue concerning one front in the relentless war which pathologists and others were waging against the biggest scourge mankind had to face

Sir LENTHAL CHEATLE then took the chair and Mr J P LOCKHART MUMMERY opened the discussion on the origin of tumours with a paper which will be found at page 785 of this issue

In opening the discussion the CHAIRMAN said that as Mr Lockhart Mummery had told them it was Boveri who in 1913 first announced a comprehensive theory that carcinoma was due to a chromosome imbalance Subsequently increased knowledge of chromosome constitution has led to the theory of the presence of genes in the chromosomes This theory had been developed and elaborated by Morgan Bauer Mottram and Ludford There were really only two concrete theories before the world of the origin of tumours One was the virus theory and the other the gene theory All one could say at present was that if Oye were right that carcinoma was due to the action of a virus then the gene theory might or might not have little to do with the matter and if it had it might be of secondary importance On the other hand if the gene theory alone were right the origin of carcinoma might depend entirely upon the imbalance of the gene elements or the virus theory among others might be incorporated in the gene theory as Lockhart Mummery suggested it could be Take for example the changes that occurred in Paget's disease of the nipple In the majority of instances of this disease there was a benign form of malignancy either in the epidermis of the nipple or in the upper duct openings When once an epithelial cell had become malignant it was with few exceptions difficult to state the origin of that cell The particular matter to which he wished to draw attention was the fact that in addition to this disease in the superficial regions there was frequently a carcinoma (which could not be regarded as a coincidence) arising in the epithelium of terminal ducts and acini He would not worry the meeting with his reasons but he did not believe that this deep lying carcinoma could be due to cell transplantation from the benign type of malignant disease in the region of the nipple The condition in the underlying and deep parts of the breast might be explained by a virus that had either passed down the mammary ducts or had reached the epithelium of the breast by the blood stream It could also be explained by the gene theory and the epithelial cells could be said to have inherited a tendency to the formation of carcinoma By some people (and Mr Lockhart Mummery appeared to be one of them) the gene theory was considered to be the best available theory at the present time and was capable of offering an explanation of all facts of carcinoma provided they were prepared to make certain subsidiary hypotheses What Mr Lockhart Mummery had done had been to give for the first time clinical evidence that might be explained by the gene theory and he had performed his task in a most impressive and masterly fashion

Dr R J LUDFORD showed some lantern slides illustrating the chromosome theory of heredity of which he said the gene theory was a special application He pointed out that the chromosome number was constant for every species of animal In man there were forty eight chromosomes in mice forty Whenever a cell divided the chromosomes split into two one half passing to each pole of the spindle The chromosomes retained their specific character with each cell division Although invisible the gene was a very real concept in biology occupying much the same place therein as the concept of the atom in physics In showing some interesting diagrams he said that if each chromosome was regarded as made up of genes and if these genes were arranged lineally then one arrived at the conclusion that at every division with the longitudinal splitting of the chromosomes each daughter cell got the same number of genes as the cell from which it was derived The gene theory of cancer postulated that some alteration had taken place in certain of the genes It was not known what alteration but it was known that the character of the cells was determined by the chromosomes—at least that was one of the foundations of the chromosome theory Of the forty eight chromosomes in man twenty four were of maternal and twenty four of paternal origin and since it was known that the chromosomes determined the physical characters of inheritance one was led to the conclusion that the particular type of biochemical process going on in the cell was the result of interaction between the chromosomes and the cytoplasm He showed diagrammatic representations to illustrate how certain mutations were transmitted by the germ cells—how for example such a defect as colour blindness was transmitted as a gene mutation This appeared to be the best method of explaining the factors of inheritance As opposed to this theory of cancer was Dr Gye's theory This postulated a ubiquitous virus which under certain conditions was able to enter the cell and confer upon it the character of malignancy The gene theory of cancer was one of the best capable of explaining all the facts as far as they concerned the cancer cell He would not say that it was actually at variance with the virus theory He believed that an open mind should be kept and that it should be realized that in cancer there might be some other process of which at the present time one had no knowledge—some fundamental biological process which with further research might be elucidated

Dr J C MOTTRAM said that his own association with this theory had not been very important Some few years ago he wrote a thesis upon it but the medical societies would have nothing to do with it The important fact which made one imagine this theory was the discovery that *x* rays greatly increased the number of genetic mutations and one naturally thought knowing that *x* rays could produce cancer that there might be a possibility that cancer was really a mutation When germ cells were subjected to *x* rays there was not the least doubt that they were altered and the same thing must happen with regard to the somatic cell Once a gene had undergone mutation the change continued for ever Only by a further mutation was this state of stability broken That rather fitted in with what was known about the cancer cell When it had been once altered it remained altered for ever Cancer cells had been cultivated for a great number of years and Jensen rat sarcoma which

he thought was the *oldest that had been cultivated, remained to-day exactly as it was when first discovered*. What was a somatic mutation? One of the earliest somatic mutations was discovered by Darwin who observed on a peach tree that one of the branches of the tree produced nectarines. What had happened was that some cell in this particular branch had become altered so that the peach had lost its furry skin and had become smooth. That had been propagated by budding, from one tree to another and had gone on ever since. There was no difference between somatic and genetic mutations. If a mutation occurred immediately after the first division of the egg cell following fertilization then half the animal would show this mutation and the other half would not. He spoke recalled many years ago when in Hong Kong, seeing a native child which was completely divided down the middle one half being brown and the other white. That was a case undoubtedly in which mutation had occurred after the first division. If on the other hand mutation occurred later in development patches of white skin would result: if very late one might have only a single cell affected. The conception of cancer on this hypothesis was that a single cell underwent mutation: it might be as a result of x rays or exposure to radium or exposure to tar or for no obvious reason at all just as mutations occurred in germ cells for no reason that could be discovered. That accord with what was found in cancer. Cancer did arise in situations where there had been no irritation and where no cause could be postulated but it occurred more commonly in cases which had been subject to irritation. If a gene in a somatic cell suffered this alteration then that alteration would go on for ever and if the alteration was such that it caused the cell to undergo rapid division cancer would be produced.

Dr W. J. Gye said that it was very difficult for him to criticize what had been said but so far as he understood the views put forward that evening they were based upon a hypothesis which was being largely exploited in biology but which was acknowledged to be nothing more than a working hypothesis. Some protozoologists disagreed with the general hypothesis as applied to biology. This working hypothesis was being made to explain a series of medical problems and thus hypothesis was being heaped upon hypothesis and analogy upon analogy until the whole thing was just a balloon. He had the fortune to be brought up as a chemist before he became a medical man and he worked for some years in that fascinating pursuit of making chemical compounds which had never been made before putting together chemical groups and so forth and one of the best organic chemists of the day used frequently to rebuke him and to say

Beware of analogies. They are dangerous. Cancer was really a pathological problem and he thought that Mr Lockhart Mummery had stated extraordinarily well some of the fundamental factors which they had to explain. If he himself had been reading his paper that evening he would have explained perhaps more in detail the character of autonomous growth. It seemed to him that neither Mr Lockhart Mummery nor Mr Ludford realized how entirely different the process of producing a tumour with a tumour filtrate was from the process of producing a tumour for example by turning a mouse. He did not think anybody would doubt who worked at these tumours that he was working on an infective process but it had very definite principles which were well worked out by Peyton Rous twenty one years ago. The work which he himself had done went to show that in the tumour filtrate there were two things which were necessary for the production of tumour—namely something which was extrinsic to the animal and something which was intrinsic. The theory developed that evening had really first been put forward by Boveri but Dr Murray, one of the most distinguished pathologists in this country and one of the acutest minds in cancer research although he had been closely associated with Boveri and had a filial regard for him could not accept his theory.

Mr Lockhart Mummery said that he had only to reply to Dr Gye for whom he felt the greatest respect. There were one or two things in Dr Gye's theory which it seemed to him the mutation theory explained. Dr Gye took a cell from the filtrate of Rous sarcoma No 1 and inoculated it into the muscles of a fowl in an extremely minute dose and produced Rous sarcoma No 1. He never produced Rous sarcoma No 2 but always No 1. It was hard to believe that that was due to an infective agent. One had the same result in the germ cell with the two minute bodies the male and the female germ cell. Dr Gye had never explained what the cell free filtrate did to the cell.

INDIVIDUAL PSYCHOLOGY

At a meeting of the Medical Society of Individual Psychology held on April 14th with the president Dr W. Langdon Brown in the chair Dr H. C. Squires read a paper entitled A novice's impressions of the theory and practice of individual psychology.

Dr Squires pointed out that the practical knowledge of psychological medicine was essential not only for the psychotherapist but also for the general practitioner. It was of value therefore to recognize the extent to which individual psychology fulfilled these requirements. A growing psychology it was far from being a rigid code with a fully formulated and finally enunciated set of principles. On the contrary its constitution like that of the British Commonwealth should be interpreted sympathetically rather than adhered to in meticulous detail. He briefly referred to several features which it emphasized such as the inferiority feeling the masculine protest and the motion of the life style and said that practical experience had led him to recognize the importance of these characteristics though of course their significance varied much from one case to another. Though understanding and appreciation of the main essentials of the practice of individual psychology was not difficult the efficient use of the method seemed to him to be quite another matter. The difficulty varied to some degree upon whether the method was used as an adjunct to other forms of treatment or whether it formed the chief instrument in other words whether it was employed for example by the general practitioner surgeon or gynaecologist on the one hand or by the professed psychotherapist on the other. One of the most important and striking features of the system seemed to be the emphasis laid upon the fact that the doctor and the patient were members of one social body towards which both had obligations. Dr Squires next alluded to certain difficulties he had encountered in the application of the technique. The treatment was not expected to be of long duration. He felt however that the novice should move slowly rather than quickly. At the same time increasing experience should enable the physician to elucidate the life plan of the patient more quickly though the most practised were as yet but feeling their way and here the use of hypotheses found its justification. From the theoretical standpoint the Adlerian system particularly appealed to him and practical experience had reinforced this bias. There was indeed much to support the possibility that individual psychology was the most practical and useful system of psychological medicine as yet evolved—a real step towards the attainment of a means for best dealing with psychological problems.

The PRESIDENT agreed that all medical psychologists are at present but groping their way. He felt that it was

ill to the good that the attitude of the school of individual psychology was not one of over self confidence and that the method was not isolated from general medicine The psychological aspect of every case must be considered if complete comprehension was to be obtained Dr T G CROOKSHANK said that one central point in individual psychology was that it dealt with the individual as a whole not as a number of fictitious entities It was important in treatment that the patient should realize that he was responsible for the action of his body Dr BEVAN BROWN doubted whether individual psychological treatment was applicable to all cases Valuable in certain superficial cases or where the patient was of good material and responded to stimulation in other instances it might make demands which were too great Dr C I ALLEN said that it was to be remarked that all methods of psychological medicine produced cures there was here subject for study Dr T LAWSON observed that exhortation was not used in individual psychology Dr O H WOODCOCK referred to the value of placing responsibility upon the patient Dr HILDA WEBER mentioned a patient who had been helped by the realization that she was ultimately a unity conflict gave to the whole the semblance of a number of disconnected fragments Dr M MARCUS said that in general practice every patient had some present problem Individual psychology was able to relieve symptoms in many cases and restore the patient to comparatively sound health

DR HUGH CABOT ON UROLOGY

At a meeting of the Devon and Exeter Medico Chirurgical Society held on April 14th with the president MR NORMAN LOCK in the chair Dr HUGH CABOT consulting surgeon to the Mayo Clinic gave an address on recent advances in urology

Dr Cabot began by saying that though much that he was about to bring forward was in the *experimental* stage considerable promise for the future could be drawn from new departures in the treatment of urinary obstruction related to prostatic enlargement Two kinds of men came for consultation in respect of this affection one was the man who definitely had obstruction while the other had made certain that he was going to have it As regards the latter this might not always be an idle fear statistics having shown that there was a strong case for heredity in benign lesions of the prostate In addition to the problem arising from the *obstructing* prostate itself there were the often associated infection of the urinary tract and the question whether the glandular enlargement was benign or malignant Turning to the plan of attack Dr Cabot remarked that there was a tendency towards a great simplification of methods From the obstructive side of the lesion they had to consider two classes of patients (1) those for whom operation could be undertaken after brief urethral drainage and (2) those who required long drainage by cystostomy For the first class (that is after urethral drainage) there was a choice of three operations (*a*) one stage prostatectomy (*b*) perineal prostatectomy and (*c*) transurethral prostatectomy with mortality rates of 8 per cent 4 per cent and 3 per cent respectively In his opinion the perineal route—a method which seemed to him to entail working in the dark—would soon be driven out of the field by the transurethral operation At the present time however the perineal choice still found support and notably by Dr Young and his disciples in the U S A In reviewing the second class of patients—those requiring prolonged drainage (by cystostomy) followed by (*a*) two-stage prostatectomy or (*b*) transurethral prostatectomy—Dr Cabot deprecated a very wide application of the two-stage operation but emphasized the importance of prolonged and efficient drainage when certain extreme conditions made this procedure essential He failed to find anything in favour of a two stage operation spaced by a few days In deciding for or against a two stage operation they had as yet no satisfactory test of renal function or any one test which informed them as to the physiological condition of more than the last third of the kidney He did not despair of the future but at the moment it was well to bear in mind that the foundations of these investigations had only just been laid The study of the specific gravity of the urine by the older physicians in association with the general appearance and condition of the man—the tip of the nose being particularly eloquent—perhaps gave nearly as much information as they could hope to derive from the efficiency tests of to day It was then for these cases of cardio vascular and renal degeneration that a two stage operation—be it a suprapubic cystostomy or per urethram—found legitimate excuse These cases said Dr Cabot *must* be drained and there were two choices in procedure (1) to enlarge the wound transversely (thus avoiding the peritoneum) and then to enucleate the prostate and (2) to perform transurethral prostatectomy In the majority of these cases the prostate would be found to have shrunk during the period of drainage but the reason for this could not be stated with certainty The mortality in prostatectomy by the suprapubic route varied from 8 per cent to 20 per cent in the hospitals of the United States while recent figures in Germany were as high as 25 per cent Incontinence and fistula had *occurred in 4 per cent* of the cases following perineal prostatectomy—regrettable and trying sequels to patient and surgeon alike The transurethral method had shown a small average mortality and though a new procedure there were now more than 1 000 cases from which *conclusions could be* drawn

Dr Cabot then related the history of various operations designed to reach the prostate via the perineum or urethra This was followed by a detailed description of the transurethral operation as now *carried out at the* Mayo Clinic and of the instruments so associated These included (1) the special make of cystoscope with diaphragm through which is introduced in turn (2) the diathermy apparatus with needles arranged so as to act upon and blanch but *not burn* the obstructing portion of the prostate (the current being run in from four to six seconds) (3) the knife for cutting out the mass determined upon and (4) the electrode for bleeding points In such an operation the small sclerotic type of prostate was likely to give the least trouble *in contrast* with the results of other operations There was no necessity to remove the lateral enlargements—those chiefly palpated on rectal examination they were not concerned in the obstruction Dr Cabot then showed photographs of removed portions of prostate stating that 5 grams represented the average weight of tissue removed in any one case The maximum and minimum required for the relief of obstruction and for pathological investigation were 20 grams and 1 to 2 grams respectively An important point was that diathermy as opposed to the cautery did not spoil the growth for subsequent section by the pathologist Following upon the operation rest in bed was prescribed for from four to ten days the average period being eight days A further operation had been required in about 5 per cent of the cases in which the patient had been unable to complete the emptying of the bladder Dr Cabot did not altogether agree with some authorities who held that this would be the only operation of the future He himself still performed suprapubic cystotomy Results however had been reassuring enough for the Mayo Clinic to recommend the

operation in 12 per cent of the cases as against 12 per cent on its inception

Turning his attention to urinary infections, Dr Cabot mentioned the remarkable coincidence in the findings of two investigators working independently in the same building of the clinic Hans Helmholz engaged in research on epileptic children produced an acid urine by ketogenic diet and noted that it remained sterile Cabot on the other hand had been experimenting with infected urine and observed that the coli group of bacilli lived but a short time in very acid urine It was discovered however that acidity of urine determined by diet had far reaching effects which was washing out the bladder and the giving of drugs such as urotropine by the mouth had proved futile Dr Cabot then showed chart which gave striking evidence of the rapid reduction in organisms by diet once acidity was established and vice versa the disappointing result of drug reached acidity and urinary antisepsis He added that although in infection of an abnormal kidney (such as congenital hydronephrosis) was once dirty difficult to clear up—and indeed at one time considered almost impossible of cure—Helmholz had succeeded by diet The same observer had found recent to be the most resistant of the organisms There was no hope for ultimate freedom from infection thus attained would last and it would be wise to repeat the treatment at definite intervals The ketogenic diet eventually arrived at through the researches of Chirs and Helmholz limited the carbohydrate intake to 20 grams but gave very high figure for fat—namely 240 grams A diet sheet arranged for twenty four hours on the lines was as follows cream half a pint bacon four slices toast four ounces Vegetable large in bulk but of low starch content supplied the carbohydrate and was given in divided serving Such a diet was capable of acid production down to pH 5 6 but it was not easy to obtain lower readings Sterilization of the urine by ketosis as a preliminary to operation appeared to be the method of the immediate future for with an obstructed bladder one could expect little relief from drugs In any case observed Dr Cabot finally the club wielded by the body is more powerful than that of the drug store and even where some success had been obtained in non obstructed cases it was a question whether this should not be returned to the credit of providence rather than to that of the chemist

The PRESIDENT in thanking Dr Cabot for an address so full of original and epoch making material remarked upon the comparatively few cases treated as yet by diathermy but an apparatus of the description mentioned by Dr Cabot was about to be installed at the Royal Devon and Exeter Hospital Dr H A LAKE inquired if ketone production by starvation had been found to be of service in urinary infection Dr R V SOLLY quoted cases of coli infection of the kidney where catheterization of the ureter and injection of colloidal soda had been followed by cure Dr R H FOURNESS mentioned a case where acetonuria treatment by an alkaline diet and pyelitis occurred in order of sequence Dr T M PRIDEAUX inquired about diuretic acid as a bladder wash

Dr CABOT in reply said that although experiments were being conducted on the effect of starvation in urinary infection no information was as yet available up to date He agreed that a definite group derived benefit from ureteral catheterization and injections but was inclined to attribute this to the mechanical effect in diminishing obstruction rather than to the injections In regard to acetonuria it had been within his early experience that diabetics were tolerant of catheterization and now the explanation seemed to hand At the same time he was not certain that pathological acetonuria and ketonuria produced by diet were one and the same

Reviews

CUNNINGHAM'S ANATOMY

The fact that *Cunningham's Text Book of Anatomy*[1] has passed into a sixth edition is sufficient evidence of the high position it occupies—a position not surprising considering how distinguished have been its successive editors and contributors how admirably they have been served by their artist and how generously by their publishers In the course of time many changes have occurred we note for example that only two of the present contributors are responsible for the sections with which they were associated in the first edition while only six of the present twelve contributors have been trained in the Edinburgh school Despite these changes however the book retains its original form and adheres closely to the plan laid down by its eponymous founder The issue of successive editions has enabled the editors and contributors to continue to record the advances made in our knowledge of the subject to add to the number and variety of the illustrations and to incorporate such suggestions as have been received in the way of constructive criticism The result is that the book is singularly complete clear and accurate

The chief changes which we have been able to note in the present edition are to be found in the sections dealing with the nervous system We find for instance that special attention is now paid to the parasympathetic system and to the innervation of the blood vessels of the limbs while in the section concerned with the central nervous system an account is given of the most recent work upon the thalamic region and its connexions illustrated by a series of new and helpful diagrams Among other changes are additional illustrations, to be found particularly in the sections on embryology the sense organs and the vascular system In the section dealing with surface and surgical anatomy figures of the lumbo sacral and sacro iliac regions from the back a pyelogram and a drawing of the palmar bursal spaces are now included That there have been so few changes in other sections must be attributed mainly to the careful and thorough manner in which these sections have been treated in earlier editions Despite its many excellencies there are a few features which in our opinion are not above criticism We note for example that in Fig 184 the coracoid element forming the upper part of the glenoid cavity of the scapula is regarded as an epiphysis whereas we contend it is no more an epiphysis in the ordinary sense of that term than are the various elements constituting the acetabulum In Figs 208 and 210 again the upper epiphyseal line of the ulna is shown passing through the great sigmoid cavity well below its upper limit whereas in the text on page 234 it is distinctly implied that this epiphyseal line lies usually outside the capsule In Fig 869 the palatine gland—the position and limits of which are usually clearly indicated by the smoothness of the area where it lies in contact with the hard palate—is shown extending too far forwards while no mention is made in the text of the relation of the gland to the crista palati

Much might be said on the vexed question of nomenclature but this is we think neither the time nor the place We will content ourselves by expressing the hope that the name epistropheus for the second cervical vertebra will be dropped and that the name of axis be again restored partly because it is to the first and not to the second cervical vertebra that the term epistro

[1] *Cunningham's Text Book of Anatomy* Edited by Arthur Robinson M D F R C S Sixth edition London Milford Oxford University Press New York W Wood and Co 1912 (Pp xxviii + 1 854 1 125 figures 2 plates 42 net)

phens is more applicable and partly because of the difficulty of forming compound words with such an unwieldy element—a difficulty evidently appreciated by the editor of the section on syndesmology who both in text and in figure uses such terms as atlanto axial and occipito axial While appreciating the pains which the editor of the section of osteology has taken to supply students with the derivation of so many names we should like to ask on what grounds he dismisses the sacrum rather summarily as a sacrificial bone in ancient times We had long been under the impression that a special and lofty fate had been reserved for this bone accounting for its name—a fate sufficiently notable to have led to its commemoration in English verse Reverting to more serious matters we wonder as we turn over the pages of this quarto volume—1 450 pages of compressed and elaborate illustrations—how a student can be expected to learn still less to remember more than a fraction of what is here presented We wonder further whether the time has not come for the writers of students textbooks on this subject to exercise more discrimination with a view particularly to abridgement and to practical application whether in fact works like Cunningham should not be regarded so far as students are concerned as reference books—books among which it is only right to say Cunningham would stand second to none

STIMULATION THERAPY IN G P I

In their account of stimulation therapy in progressive paralysis Professor K BONHOEFFER and Dr P JOSSMANN give the results obtained with the treatment of general paralysis by malaria infections and other fever producing procedures According to Jossmann 2 000 cases were treated in Berlin from 1922 to 1929 by the use of the Wagner Juregg malarial inoculations Of these 23 per cent were classed as cures and a total of 40 per cent were definitely improved The results recorded in Germany and other countries are tabulated and show that the successes claimed vary from 6 to 49 per cent The author mentions that the literature on the subject now amounts to some 3 000 articles The chief conclusion of importance is that Reiztherapie has attained successes in cases of general paralysis that cannot be paralleled by any previous form of treatment Dr Kellmann in his contribution acknowledges the remarkable successes of malarial therapy but points out that it cannot be stated to conform to the *nil nocere* principle since it undoubtedly kills a certain proportion of patients Alternative pyretic measures that have been investigated are inoculations with recurrent fever and injections of sulphosin The latter which is a suspension of sulphur in olive oil produced nine cures in fifty four cases It has the advantage of being easily controlled and safe and Kellmann remarks that even if it is found to be inferior to malarial infection in potency it will nevertheless find a field of usefulness in the treatment of debilitated patients for whom more drastic therapy is too dangerous The remaining articles in the volume deal with other forms of stimulation therapy and the pathology of general paralysis

PATHOGENESIS OF PULMONARY TUBERCULOSIS

Professor LEON BERNARD has inaugurated a proposed Bibliotheque de Phtisiologie with a study entitled *Les Débuts et les Arrêts de la Tuberculose Pulmonaire*[1] It is a book which will appeal only to the advanced student of tuberculosis and will not be of much interest to the ordinary medical student or to general practitioners save those who are making an intensive study of this disease Views on the pathogenesis of pulmonary tuberculosis would be a more descriptive title of the work and all who are interested in this subject should certainly read it That they will probably not agree with a great many of the author's conclusions does not matter they will get some new problems presented to them in an attractive way and many of the old ones will be seen from a different angle There is so much controversial matter in the work that a detailed criticism is out of the question The second chapter on primary infections in infants children and adults is the best and the author's five rules governing the interdependence of infection and disease are probably sound and valuable From this point onwards the work deteriorates The conclusions drawn are based apparently almost entirely on x ray appearances into which much more has been read than we should think permissible and the examples given in the reproductions are not at all convincing But still Professor Bernard has been studying tuberculosis for many years and anything that he has to write on the subject must be carefully considered Why he finishes up this purely anatomico pathological study with a chapter on tuberculosis and marriage is difficult to understand The book itself is the usual paper covered French production ill bound with pages of all sorts of sizes issued uncut and difficult to handle

BIRTH CONTROL

There is a handy little book called *A Guide to Birth Control Literature*[2] compiled by NORMA E HIRES It is a selected bibliography on the technique of contraception and on the social aspects of birth control Under these two main headings references to a number of American and English publications are given and a third part gives similar references mainly to German publications There is said to be no birth control literature worth mentioning in French Italian or Spanish Such a guide will be useful to some The largest number of items under one name occur under that of the compiler The Baedeker system of asterisks is adopted and an examination shows it to be not only up to date but prophetic for the only two items marked with a double asterisk are volumes not yet published of one of which it is said that it will be a complete source book and of the other of which it is said that it will be undoubtedly the best short treatise yet published It is of course possible that this may lead readers to wait for these instead of reading those already available Nevertheless two of the most recent of these others (with only a single asterisk) are worth notice—Dr A TOINETTE KONIKOW'S *Physician's Manual of Birth Control*[3] and *The Practice of Contraception*[4] an international symposium edited by MARGARET SANGER and HANNAH M STONE

In her introductory chapter to the former of these the author writes The physician who a few years ago looked upon birth control as something beneath his dignity now wants information and eagerly examines the books written by those with experience This is largely true and the manual —not in its literal sense a very good description—will provide the practising doctor with a clear account of alternative methods with definite reasons why one of these has been adopted by the author

and with a practical exposition of the exact technique followed. One or two of the chapters would be regarded in this country as altogether too elementary for a book intended for qualified medical practitioners and too much importance need not be attached to the statistical section. The second of the two books named above is a report of the papers read and the discussions which followed at the Zurich International Birth Control Conference in 1930. Here can be found a full and critical account of all the varieties of contraceptive method including sections on sterilization and abortion with instructive and often destructive comments by persons entitled to make them. There are also clinic reports from the United States, England, Germany, Austria, Holland, Denmark, with some account of work in India, China and Japan, and a section on birth control and abortion in Soviet Russia. A useful summary by Dr. Stone completes a volume which contains a large amount of reliable information on the subject with which it deals.

We have received also two interesting reports—one from the Society for the Provision of Birth Control Clinics and one from the Birth Control Investigation Committee. The former is entitled *Birth Control and Public Health* and gives some account of the ten years' work of the society. The latter is the fourth annual issue of the International Medical Group for the Investigation of Contraception.[8] It contains some particularly valuable articles and illustrations and notes on research, and as might be expected from the auspices under which it is issued these are marked by knowledge and impartiality. There is a special study of the Grafenberg ring method. To the former of these two reports there is a preface by Professor Julian Huxley dealing generally with the birth control movement. It is difficult to understand his points: they seem exaggerated and contradictory. Perspective seems to have been lost. For the relief of suffering and misery, for the prevention of destitution and degradation, it is possible that there are matters of more moment than birth control. If ignorance, superstition, unduly and poverty are the chief factors responsible, would it not be preferable to try and remove them, perhaps by methods even more effective than birth control?

In the present state of our knowledge research is required more than excitement. At any rate from a perusal of these publications it is clear that there are great gaps in our knowledge, that dogmatism is unjustified, that the perfect contraceptive method has still to be discovered, that some methods at present employed are definitely harmful and others have yet to be proved harmless, and that all the available statistics are highly unsatisfactory and many of them entirely unreliable. It may be added that the ethical and social effects of a widespread use of contraception are by no means certain. Even an enthusiast like Dr. C. P. Blacker has to conclude his contribution thus:

> It is necessary to discover a method that is wholly dependable, harmless, fool-proof and aesthetically unobjectionable. But the popularization of such a method will not be free from grave racial dangers. It will be for the moralist and eugenist of the future to guide us past these dangers. Every practical advance in the application of negative eugenics, i.e. the limitation of the fertility of the ill-endowed, must be accompanied by a fresh emphasis on the necessity of positive eugenics, the encouraging of the reproduction of the healthy and fit. Every advance in our knowledge of genetic processes is accompanied by dangers. The dangers that will accompany the popularization of ideal [illegible] for the [illegible]alworthy

THE USE OF THE SELF

In our issue of May 24th 1924 (p. 913), we reviewed a book by Mr. F. MATTHIAS ALEXANDER entitled *Constructive Conscious Control of the Individual*, in which the thesis was developed that man tends unwittingly to use his psycho-physical mechanisms imperfectly in his endeavour to adjust to the complex conditions of modern life. The same author has now written a smaller monograph *The Use of the Self*[9] in which he illustrates the principles outlined in his previous book by giving instances of imperfect adjustment and at the same time describing the technique he has evolved by means of which the faulty reactions may be inhibited and new and efficient ones built up in their place. It is the essence of Mr. Alexander's teaching that too much reliance is placed upon instinctive and habitual modes of reaction which are frequently faulty and ineffective, and it is quite understandable, as he takes much pains to explain, that the teaching of a new reaction is extremely difficult as to the pupil it feels wrong though actually right. This is an eminently practical book and the author's theory and practice are clearly the outcome of many years' work. One chapter is concerned with the golfer who cannot keep his eye on the ball, another with the stutterer and a third with diagnosis and medical training. The book will be found helpful and suggestive to both the medical practitioner and the educationist.

NOTES ON BOOKS

The third edition of *The Practice of Medicine*[10] by Professor A. A. STEVENS has been entirely revised and reset and the list of sections new or altered is necessarily long. In the five years approximately which have elapsed since the last edition certain new diseases have been recognized or rarer ones have become more common so that sections have been added—for example on psittacosis, lipoid nephrosis and cystic disease of bone associated with parathyroid tumours. In other directions advanced knowledge about aetiology and therapeutics has led to modifications as in rickets, Gaucher's disease and disseminated sclerosis. Sampling of the book has given very satisfactory results although here and there a certain vagueness makes the author's meaning doubtful. For example in rickets an exposure to artificial ultra-violet radiation twice weekly for eight months is recommended but whether this prolonged course is for prophylaxis or cure is not clear and in either case it seems unnecessarily lengthy. Numerous footnotes throughout give references to monographs and more extensive information on many subjects. These enhance the value of the book. It needs no introduction in this country and the new edition will be welcomed by those who require a complete and readable textbook.

The work on *Fertility and Sterility in Marriage*[11] by Dr. TH. VAN DE VELDE formerly director of the Gynaecological Clinic at Haarlem forms the third and last volume of a series of which the first two were entitled *Ideal Marriage* and *Sex Hostility in Marriage*. The book is divided into three parts. In Part I which deals with postulates and principles the author discusses the ethical and theological aspects, family limitation in its national, international and racial aspects and the individual aspects of fertility and sterility in marriage. Part II which is entitled [illegible] The achievement of desired pregnancy, con[illegible] chapters on the physiology of reproduction, the [illegible] of sterility

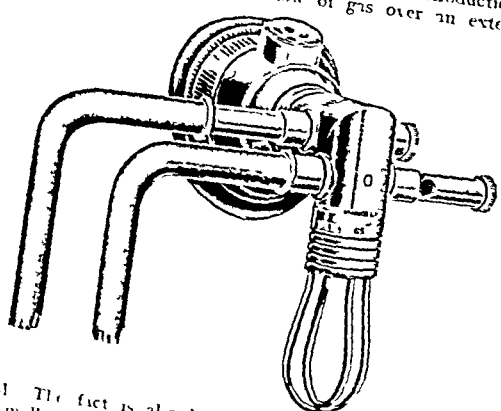
in women and of impotence in men and artificial fertilization or insemination Part III which is devoted to the prevention of undesired conception contains chapters on contraceptive mechanical and chemical appliances and permanent or temporary sterilization A bibliography of 917 references to scientific theological and other literature is appended The sale of the work is limited to medical practitioners biologists psychologists sociologists and representatives of scientific education and research



Coming from so distinguished an author as Hofrat Professor Dr HANS SPITZY a little work on Orthopaedics in General Practice[1] cannot fail to be of value restricted as its scope may be The series to which it belongs professes to provide for the practitioner a scientific basis for his work and practical application of principles As most of the conditions described are not common they are not likely to be met with often by any one general practitioner If he has this booklet by him however he will be able to find help in diagnosis and treatment for which latter he will probably in the end refer to a specialist

PREPARATIONS AND APPLIANCES

GAS AND OXYGEN IN MIDWIFERY

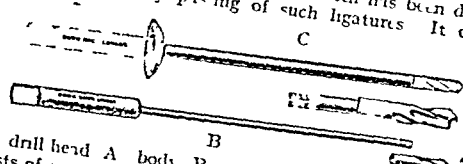
Dr C R POTTER (Barnsley) writes The value of nitrous oxide and oxygen as an anæsthetic has been recognized for many years but mechanical difficulties of administration have militated against its more general use These difficulties have been much lessened in recent years by the introduction of valves which give an even flow of gas over an extended

period The fact is also becoming more and more realized that small quantities of other anæsthetics can be administered with advantage in combination with gas and oxygen One of the best known is made by Dr S Thompson Rowling in which chloroform is made by a special apparatus and either ether chloroform or both The writer having had an anæsthetic table gas and oxygen being passed through it for some time chloroform or both The writer having seen the good result obtained wondered if the idea simplified could be brought within reach of the general practitioner particularly for use in midwifery

The method tried has been to fit a gas and an oxygen cylinder with Hoke valves and connect these each by a separate rubber tube to a Clover ether apparatus the bag of which is fitted with two slot valves one for each rubber tube The two valves which are fitted to the angle piece holding the bag enable either gas or oxygen or both to be given in any quantity Ether can of course be turned on and off at will This simple and portable apparatus enables gas and oxygen to be given alone with the face piece if required for operative work or for the induction of instruments the other chamber may be used To illustrate the use of the apparatus the four following cases might be quoted

1 A multipara aged 28 years healthy third child Natural delivery 8 hours Gas and oxygen with face piece given for each pain for two hours

2 Patient aged 38 years second child Preliminary dose of sedative for first stage Gas for each pain second stage Instruments when head on perineum Gas oxygen face piece and bag only

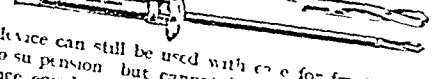


3 Obstructed labour cervical fibroid Pyrexia 38 degrees Cæsarean section Induction by gas and oxygen then ether Gas and oxygen for sewing up abdominal wall Time taken forty minutes

4 Multipara tenth child Transverse presentation hand presenting Gas oxygen and ether for a few minutes Foot brought down Natural delivery two hours afterwards

The pleasing feature has been the absence of shock and hæmorrhage in all cases In addition the use of such small quantities of ether makes for safety in bedrooms with open fires and gas jets The slot valve is made by Messrs Reynolds and Branson Ltd Leeds

BONE DRILLS



Mr A SIMPSON SMITH MCh FRCS writes The passing of wire fascia or tendon through bone is often beset with difficulty The instrument shown herewith has been designed to facilitate the easy passing of such ligatures It consists

of a drill head A body B and cannula C The body B will fit any standard bone drill whether of the Colt or Archimedean pattern as shown or of the chuck pattern the jaws of which will grip the shoulder immediately beyond the step end The shaft has a tip with a reverse screw threaded end to receive the detachable drill head A The cannula C exactly fits over the shaft between the head and shoulder and is of slightly smaller diameter than the drill head The assembled drill is passed through the objective bone so that the drill head just clears the opposite side An assistant immediately grasps the drill head A with a Lane's screw holding forceps or other suitable tool The surgeon reverses the drill action thereby releasing the drill head and then withdraws the parent drill with the shaft B attached in one movement Thus in *quick* sequence of drilling reversing and withdrawing a cannula is left in the bone through which the desired wire or ligature can be passed Withdrawal of the cannula completes the operation

This device is not only very applicable to the binding of patella fragments but in fractures of the long bones of the limbs where open reduction alone almost produces a stable reduction binding material (of fascia autogenous tendon or wire) can be readily introduced to effect this end The small drill head enables comparatively deeply situated bones to be so drilled for with a small clearance—the length of the drill head—is necessary on the contralateral side to the one easily exposed In the operation of tenosuspension for recurrent dislocation of the shoulder as practised at the Mayo Clinic should the surgeon so elect this particular operation the introduction of the tendinous sling is very easy

Five years ago Messrs Down Bros prepared a drill for me with the head and shaft made as a single unit and fitting into a shoulder for universal attachment to all bone drills

This device can still be used with ease for fractured patella and tenosuspension but cannot be used when there is not a clearance equal to the whole length of the shaft and head on the contralateral side of the bone Its usefulness therefore only very limited and chiefly applicable to the patella Mr Herbert Paterson brought to the notice of the profession a drill somewhat similar to this earlier pattern

My thanks are due to my colleague Mr E C Hughes MCh for allowing me to use this drill on cases under his care To Messrs Down Bros for their courtesy and patience in the preparation of numerous bone drills during the past five years until this final product has been selected I owe every acknowledgement

CARDIO-VASCULAR SYPHILIS

No disease is more subtle variable and unexpected in its manifestations than syphilis But while the infection may operate at times when it is least anticipated, there are circumstances which strongly suggest its presence Among circulatory disorders it is reasonable to suspect the spirochaete in aneurysm sudden death, and sometimes in angina and heart block Conversely there are certain factors which render syphilis unlikely as a causal agent Thus symptoms occurring before the age of 35 are unlikely to be caused by this infection while the coexistence of auricular fibrillation is so uncommon that in a group of 575 patients with this arrhythmia McEachern and Baker[1] found syphilis to be an aetiological factor in only eighteen Myocardial infarction is another malady to which syphilis an frequently contributes The manifold and obscure problems of cardio vascular syphilis have recently been illuminated by Dr Carey Coombs in a masterly review Dr Coombs finds no convincing evidence that the disease is becoming more frequent and he suggests that the following decade will show whether or not our modern anti syphilitic measures are of avail in reducing the liability to specific aortic lesions The high incidence of primary syphilis during the early post war years indicates that unless treatment has been successful there will be an increase in the late effects upon the aorta and the heart between 1935 and 1940

There can be little doubt that the characteristic aortic involvement is due to the spread of toxins from reservoirs in the mediastinal lymphatic glands Dr Coombs now develops this view, to which he has previously[2] subscribed He mentions the fact that it is a general lymphadenitis which brings the stage of bacteriemia to a close in syphilis and refers to the experimental work which has demonstrated the persistence of living spirochaetes in the lymphatic glands for months or years after an animal has been inoculated with the disease Further, in general paralysis—a disease that has many features in common with aortic syphilis—the lymph glands were found to be infective in three out of fourteen cases by Engmann and Eberson[4] In his consideration of the early diagnosis of aortic involvement Dr Coombs postulates that probably every person infected with syphilis sustains some aortic damage within a year or so of the infection Since in the earlier stages it is clear that physical signs must usually be lacking he turns to radiography and electrocardiography as diagnostic aids The latter has failed to provide any special clues Examination by x ray however, is believed to be of great use in the early diagnosis of aortitis, widening of the aorta—especially if unaccompanied by cardiac enlargement—increase in its opacity, or decrease in its pulsatile excursion all being regarded as important indications One which is less generally remarked upon, but which is also of undoubted value, is the elongated arc presented by the aortic knuckle when this is the seat of syphilitic inflammation Dr Coombs aptly states the case when he says that 'skiagraphy can often clinch a diagnosis of aortic syphilis when nothing else can, by proving that the aorta is enlarged in circumstances justifying a belief that the enlargement may be caused by syphilis"

Apart from symptoms signs and radiography, the therapeutic and serum tests may be of diagnostic consequence Although, theoretically a response to anti syphilitic treatment might be of help in diagnosis such a result is rarely so pronounced as to justify the inference Nor is the Wassermann reaction of as much value as has been supposed in past years The consensus of opinion is that a negative reaction may be obtained in about one third or one quarter of patients suffering from cardio vascular syphilis, that such a reaction does not exclude the diagnosis, but that a positive result is of great significance if the clinical context is appropriate There is some evidence suggesting that the flocculation tests are more reliable in this connexion than complement fixation and the Kahn test might therefore be profitably applied in doubtful cases Dr Coombs summarizes the treatment of cardio vascular syphilis by insisting that an attack should be made on the spirochaete from the moment of diagnosis and for the remainder of the patient's life whether or not symptoms or signs are present Iodide and mercury are nearly always applicable but arsenic is contraindicated in advanced aortitis and when there is evidence of coronary stenosis That Dr Coombs regards the treatment of cardio vascular syphilis in no spirit of false optimism may be judged from his concluding remark that by the time changes become appreciable to the clinical observer "the damage done is already considerable and largely irreparable'

MEDICAL RESEARCH AND THE PATENT LAW

The fundamental object of the patent system has been defined as the promotion of new industries and the improvement of old ones by the grant of temporary monopolies to persons responsible for discoveries and inventions upon which the new industries or improvements may be based In other words, it is primarily economic, and its relation to medical science is at first sight remote It has generally been assumed in this country at least alike by the profession and by the public at large that medical workers will be unwilling to derive direct profit from the limited monopoly conferred by patent rights in respect of discoveries and

inventions in the medical field The consequent refusal of medical workers to use the machinery of the patent law has tended in the past to obscure the fact that modern developments in the scope and methods of scientific research on the one hand and in the relation between science and industry and commerce on the other have given patent law and practice an important bearing upon the progress of medical science and created practical problems and difficulties whose solution requires something more than the simple affirmation or repudiation of the traditional ethical objection to monopoly and secrecy in the scientific field If the results of medical research are to be made immediately available to the public it will only be by the co-operation of commerce and industry in the production and distribution of new therapeutic agents Due account must therefore be taken both of discoveries and inventions of importance to the development of medical science which emerge as incidents of research directed primarily to other ends and of the possibility that discoveries made in the course of medical research may have economic applications beyond the therapeutic field It is clear also that any ethical principle which is to command the continued allegiance of the profession as a whole must be generally acceptable to those most closely concerned—that is to say to medical men and women engaged exclusively in research whether independently or as members of the salaried staffs of institutions and it must allow for the constant association on generally equal terms of medical and non-medical scientists on the staffs of such institutions Nor must it be forgotten that the use now being made of patent rights in this country by foreign nationals acting under existing international conventions has further complicated a position which is from the nature of the case by no means simple

The Council of the British Medical Association has been engaged since 1929 in an attempt to bring the traditional professional usage into harmony with modern conditions It will be remembered that the Representative Body—which refused in 1930 to endorse the proposition that it is ethically undesirable for a registered medical practitioner who makes an invention or discovery in the medical field to derive financial benefit from the sale of the rights of such invention or discovery or from royalties for the use of these—adopted by repudiated in 1931 a formula which while condemning undue restriction of the use and knowledge of discoveries or inventions likely to be of value in the treatment of patients for the personal advantage of the medical worker recognized the propriety (subject to the safeguarding of that principle) of the utilization of arrangements made by law for the protection of such inventions or discoveries by patent or otherwise For this it substituted a resolution which approved the traditional professional usage but left still undetermined its application to the particular question of patenting It is hoped that the conference reported at page 206 of this week's *Supplement* which met at the House of the Association last week has carried the whole problem a step nearer to solution Meanwhile the omission from the Patents and Designs Bill (which was introduced by Lord Templemore on April 21st and passed its second reading in the House of Lords last Tuesday) of any provision for easing the situation so far as medical research in this country is concerned emphasizes the need for a speedy and general agreement by the profession on the points at issue That omission is not surprising The Bill is based on the recommendations of the Departmental Committee of the Board of Trade whose report published last year dismissed the careful analysis of the position presented by the Medical Research Council with the cavalier comment

If in general the disadvantages of the monopolies granted by a patent system are more than counterbalanced by increased stimulation of industry and invention we see no reason for thinking that the same result should not equally obtain in this particular field' This verdict would seem to ignore the reasons given by the Medical Research Council for the contention that existing patent law is not well adapted to the stimulation of invention in the field of biological and medical research and that consequently the same result does not in fact obtain in that field of work

But if the Departmental Committee in its preoccupation with the economic and legal aspects of patent law failed to appreciate the possible reaction of that law upon scientific research there is the more reason for our profession to study most carefully the representations made by the body charged by His Majesty's Government with the duty of promoting medical research The Medical Research Council's memorandum now available as an appendix to its report for 1931–32[1] supplies a concise review of the facts which must be taken into consideration in formulating professional policy In view of the importance of the subject we propose to publish a detailed abstract at an early date

CRIMINAL STATISTICS

The fascination which crime has these days for all classes of the community will provide an interesting psychological study for the social historian of the third and fourth decades of the present century Coincident with this fictional concern in crime and the criminal on the part of the general public there has been a disquieting increase in actual crime which has shown itself especially among juveniles and young adults In his introduction to the Home Office report on Criminal Statistics for England and Wales in 1930 Sir Arthur Locke refers to the survey made in the report for 1928 which showed that while there had been since the war a diminution in the number of crimes of violence against the person and the grievous assaults on women the number of crimes against property—especially breakings in larcenies and frauds—had grown to such an extent as to pass the pre-war level The tide of crimes against property rises higher

[1] Cmd. 4065 H.M. Stationery Office. 2d. net.
[2] Criminal Statistics England and Wales 1930 London H.M. Stationery Office 1s. 2d. (1s. 6d. net.)

each year the figure for breakings and similar offences having in 1930 exceeded that for 1929 by 5,256. Two-thirds of all persons found guilty of crime are of ages below 30. It was pointed out in the introduction to the report for 1929 that the two main social factors responsible for this were the industrial depression in the North and the fact that the persons now under 30 years of age were below the age of 16 in 1917, a time when parental control, owing to war conditions, was at its lowest. Moreover, this section of the population has grown up during a period when crime has been forced into a romantic setting by the stage, the cinema, and the detective novel. The social anarchy prevailing in America has been treated by the popular press as good selling stuff; the financial adventures of Al Capone and the transatlantic flittings of Jack Diamond are looked upon as exploits worthy of Crœsus and Marco Polo; the rum-runner is as gallant a figure as Drake, whom the Spaniards called the English pirate. In the American film the policeman is slow of brain and outwitted by the nimble-fingered and quick-thinking thief. In the daydreams of the modern youth the gangster has usurped the throne of Sexton Blake and Sherlock Holmes. Is it, then, other than surprising, when the temptation of the preponderance of crime to the young continues year by year, in spite of the fact that the numbers of the mature and aged elements in the population are constantly swollen by the increased expectation of life, while the numbers of the young are depleted by falls in the birth-rate? This is a state of affairs for which society cannot be completely absolved from blame. The courts becoming aware that "to make the punishment fit the crime" is not so simple a matter as was once thought, have made fuller use of the Probation of Offenders Act, and have at last begun to doubt the value of corporal punishment as a deterrent to the criminal. At the same time longer sentences of imprisonment have been passed. Referring to the altered policy of the courts Mr. Locke remarks that "too much must not be hoped for from any such change." While the function of the law is mainly in the detection and punishment of crime, the responsibility for shifting the social scene in which crime is made possible lies with society itself. This is undoubtedly a tall order, but even a little could be done, for example, by reporting criminal activities briefly and in small type instead of in large type with glaring headlines. A comparison of statistics for the North and the South shows that the industrial depression has had its worst effect on children in the North and on young adults between 21 and 30 in the South. The South, being more prosperous, affords better opportunities for the more serious crimes against property with violence, the motor car being an important part of the criminal's equipment. In the South, too, it may be noted, there is a higher number of crimes of violence against the person. In the introduction to the report for 1929 Mr. Locke came to the conclusion that "the general outlook appears to be not unfavourable." The tone of the present introduction does not appear to be so optimistic. Much would seem to depend on the lifting of the industrial depression, and much also on the extent to which the Americanization of the criminal world will go. A change of attitude would hold out better prospects of recovery than changes in judicial procedure.

BRAIN AND MIND IN EAST AFRICA

In a recent communication[1] Dr. Sequeira has summarized the work which Dr. H. L. Gordon has been carrying out during the past two years on the brains of East African natives, a work which has more recently been supplemented by the researches of Dr. F. W. Vint at the Pathological Laboratory in Nairobi. The researches centre on the cranial capacity and weight of the brain of East African natives and on an examination of the layers of the frontal cortex, based on similar investigations by Professor Shrubsall-Bolton, Professor Berry, and the late Professor von Economo. The conclusions which have been reached indicate the presence of a low degree of mentality and suggest that, owing to a peculiarity of the architecture of his brain, the African differs mentally from the European, not only in degree but very definitely in kind. Indeed, Dr. Gordon is quoted as saying that "in the first series of brains examined *micro-scopically only 6 per cent.* appeared to approach in *quality* the average of the European brain, and not one was above that average." These conclusions, if they are scientifically valid, open up questions of the greatest importance. As Dr. Sequeira justly observes, if it is proved that the physical basis of "mind" in the East African differs from that of the European, it seems quite possible that efforts to educate these backward races on European lines will prove ineffective and possibly disastrous. It is not only the physical basis of mind, however, which makes such an attempt nugatory, but the profound contrast in culture and environment which rebels against the abrupt substitution of one standard for another. If there is this alleged physical difference in the structure of the brain it would only serve to make still more impossible an assimilation which is already culturally difficult because it would mean that there could never be any hope of the African thinking in the same way as we do ourselves. And yet it is suggested in the same communication that, despite the physical differences to which these researches point, "it might be possible to determine how far environment, educative influences, etc., might overcome inherited character." This implies that mind and the structure of the brain are not necessarily correlated, and that brain formations which are taken to indicate a backward or defective mentality are not a permanent handicap to mental development—a position which appears to cut at the roots of the kind of scientific research which is being conducted in East Africa. While every credit should be given to Dr. Gordon for privately undertaking investigations which should be carried out with State assistance, we feel nevertheless that the conclusions drawn are perhaps premature. The correlation between the infragranular, granular, and supragranular layers on the one hand and "the animal instincts," sensory perceptions, and the intellect on the other cannot be accepted as an established fact. It is, we suggest, overbold to state that "in the East African therefore animal instincts are provided with 6 per cent. more physical basis than in the European, but the physical basis of mind shows a preponderance in favour of the European of 9·3 per cent." A more serious objection, however, lies in the classification of

[1] *British Medical Journal*, March 26th, p. 581.

the East African who is contrasted with "negroid" though to the best of our knowledge all East African tribes are negroid. When it is affirmed that there are not only remarkable physical differences between the East African and the European, but that there are striking variations in different tribes'—a proposition to which we cordially assent—it is difficult to see how the East African can be classified as a group in contrast with caucasoids, negroids etc. Not only do the tribes show remarkable physical differences between each other but there is a wide range both of physical and of mental variation within a single tribe. In view of this it is relevant to ask for further details before any conclusions can be even tentatively accepted. What physical measurements and physiological tests have been made? From what tribes was the material drawn and did it represent any particular section of the community—hospital patients for example or prisoners? What in short are the specific data on which these observations are based?

DANGEROUS DRUG TRAFFIC IN EGYPT

The report for the year 1931 of the Central Narcotics Intelligence Bureau of the Egyptian Government affords abundant evidence of the over production of dangerous drugs and of the illicit traffic which thereby results. T. W. Russell Pasha who in 1930 staggered the League of Nations Committee by the disclosures he vouchsafed of smuggling gangs at work in Europe has continued his vigilant detection of illicit traffickers in morphine, heroin and hashish. An important source of such traffic was shown to be the three foreign owned factories in Stamboul. So long as Turkey a large producer of opium and in recent years of morphine and heroin also, is unbound by the opium Conventions of 1912 and 1925 there is little prospect of restricting the use of these narcotics to medical and scientific purposes. It is indeed alleged with some assurance that no less than ten tons of these drugs of Turkish origin passed into illicit traffic in 1930–31. Pressure has been brought to bear both by Russell Pasha and the League of Nations upon the Turkish Government and it is stated that one of the Stamboul factories has been closed that a monopoly of narcotics is to be established and that in future the export trade is to be rigorously controlled. It would however be rash to conclude that the scandals which have been exposed will entirely disappear with the control measures which have been decreed. Last May Russell Pasha represented Egypt at the Geneva Conference on the Limitation of Manufacture of Narcotics. He contributed a racy speech to the proceedings and pointed his insistence on the ghastly side of narcotic addiction by the exhibition of photographs of smugglers' contrivances and of a film showing the physical miseries of drug addicts. His annual report for 1931 is similarly illustrated and gives numerous instances of large seizures of heroin, hashish and opium effected by the effective vigilance of the preventive authorities under the Narcotics Bureau. Though narcotic addiction is said to have been much reduced in Egypt it is estimated that there are still some 250,000 out of 14 millions who are slaves to the habit. While Russell Pasha considered the last Convention which emanated from the Geneva Conference of 1931 to be an improvement on previous efforts he remarks that it is not the Convention of Direct Limitation which some of us hoped to see. It will be remembered that the Assembly of the League regarded the last Convention as but the first step towards the limitation of the production of the raw materials—that is of opium and the coca leaf. This conclusion has been reinforced by the findings of the League's Commission which visited the Far East in connexion with the use and abuse of opium for smoking. The inclusion of the raw materials within the circle of limitation and the effective concert of the chief producing countries would appear to be essential to the restriction of the dangerous drugs in question to medical and scientific purposes. This has been the objective of all the Conferences which have been held and of the Conventions drafted during the last twenty years.

A NEW ERUPTIVE FEVER?

In a communication recently made to the International Office of Public Health Professor J. Cantacuzene[1] the Rumanian delegate gave the following account of a new eruptive fever which was first observed by Dr. Stroe in a creche at Bucarest in 1923 and had occurred in that city on several occasions since the last outbreak being in October 1931. The incubation period of this disease which had been named infantile miliariform exanthem was generally ten to fifteen days. The period of invasion lasted two to five days the first symptoms being a rise of temperature ranging from 100·4° in the mild cases to 103·2° in more severe attacks. The most striking symptom of the period of invasion was generalized and profuse sweating accompanied by a slight facial enanthem and a papulo vesicular eruption on the buccal mucous membrane, oculo nasal catarrh, restlessness and insomnia. As a rule the temperature fell on the appearance of the rash which ordinarily started on the face and then became generalized. It was usually scarlatiniform but sometimes morbilliform. The rash which soon became complicated by a profuse eruption of miliary vesicles was slightly pruriginous. Its duration was two to three days in mild cases and six to seven in the more severe and the subsequent brawny desquamation lasted four to five days. In severe attacks there was a predominance of nervous symptoms such as extreme restlessness and clonic convulsions with marked hypertension of the cerebro spinal fluid. The average duration of the disease was five to six days but in some cases it might last more than three weeks when two or five relapses separated from one another by intervals of four to five days might occur. The case mortality averaged 4 per cent. The blood picture was characterized by a monocytosis with a high degree of eosinophilia. The injection of serum of convalescents from the disease in scarlet fever patients in the eruptive period produced extinction of the rash but the reverse did not take place. The cerebro spinal fluid remained clear and only 1 to 3 lymphocytes were found per cubic centimetre. Post mortem the most constant lesion is enlargement of all the lymph glands as in scarlet fever. There is hardly any enlargement of the spleen. The nerve centres show

[1] Bull. Office Int. d'Hyg. Publique.

considerable hyperæmia of the meninges On histological examination the only characteristic lesion is invasion of the dermis by mononuclear leucocytes On the first appearance of the disease the possibility of scarlet fever was considered but this was excluded by the profuse sweats during the period of invasion the absence of characteristic desquamation the occurrence of relapses and the mononucleosis in the blood and skin The disease appears to be a special form of sweating sickness differing from the classical type in that it is strictly confined to children the extreme limits of age being 2 months and 10 years Scarification of the cornea of rabbits with virus contained in the miliary vesicles gave rise to myeloloma epiphoriform attacks photophobia and profuse salivation but never keratitis The infected cornea remained virulent for four days but the virulence became rapidly attenuated on successive passages through animals The brain of children in fatal cases show no virulence

THE J B MURPHY ORATION

Sir W I de C Wheeler Dublin has accepted the invitation of the Board of Regents of the American College of Surgeons to deliver the Murphy Oration in surgery at the opening meeting of the Clinical Congress to be held in October next The first John B Murphy Oration in surgery was delivered by Lord Moynihan in 1920 and he was followed in subsequent years by Dr William J Mayo Professor Rafaele Bastianelli Dr George W Crile Drs N D Royle and John I Hunter Sir Arbuthnot Lane Professor Archibald Young Sir John Bland Sutton Professor Vittorio Putti Professor D P D Wilkie Professor G Grey Turner and Professor Arthur H Burgess

THE PLANNING OF LABORATORIES

So much time can be lost and so much annoyance caused by ill designed laboratories that no amount of care in their planning can be too great Considerable difficulties however stand in the way of those who are called upon to carry out such a task Though they may be experienced and fertile of ideas it is almost certain that they will want to see or know what other people have achieved in their field a desire entailing numerous visits to laboratories and a close study of all the available sources of information In this state of affairs Mr A L Munby's book *Laboratories their Planning and Fittings*[1] should come as a welcome and time saving aid to them His treatise is general in its scope After dealing with the inception of building schemes he passes to a consideration of the requirements in the case of chemistry physics and biology Laboratory services gas water electricity heating ventilation drains cold storage plants, are all discussed while his final chapter gives detailed and illustrated examples of laboratory design The information which has been drawn from different parts of the world concerns the needs of both school and university equipment and the contents of the book have been brought well up to date A second step in the right direction—and one which should encourage a better understanding between the promoters and designers of laboratory buildings particularly in respect of fittings finishings, and supply services—is to be found in a questionary emanating from the Royal Institute of British Architects This is to be sent to the heads of departments in the universities of the British Empire and to certain research institutions Its clear and well designed form aims at securing a consensus of opinion (of a statistical nature) on the ideal requirements of a scientific laboratory Should analysis of the returns justify it the R I B A proposes to issue a short report This would place architects and engineers in closer touch with existing laboratory needs and perhaps help promoters of buildings to crystallize their ideas

NEW POTTERY REGULATIONS

The heavy incidence of silicosis among potters millers and workers in potters' shops and other branches of the china earthenware electrical ware and tile potteries shown by the report of Drs Sutherland and Bryson (to which reference was made in our issue of November 14th 1926 p 901) called for action And where silicosis schemes have been enacted as is the case with pottery manufacture the wise practice of the Home Office has been to prepare regulations to control the risk as far as possible How necessary they are is shown by the fact that in the china and earthenware industry alone in 1930 compensation amounting to over £29 000 was paid for ninety eight new cases for thirty six cases carried on from the previous year and for thirty four deaths These Draft Pottery (Silicosis) Regulations enlarge the existing wide reaching code for the manufacture and decoration of pottery but are made to include also premises in which flint is ground Their main feature is the provision of efficient exhaust ventilation for a variety of processes such as crushing, grinding and sieving of flint all processes involving exposure to powdered flint the fettling of ware and the placing of plates cups and saucers in powdered flint in the course of china manufacture A bewildering number of processes capable of giving off harmful dust are mentioned and an alternative to exhaust ventilation which is freely allowed is the carrying out of the process by a wet sponge or while the ware is still moist What sounds a particularly dusty process is the crushing or grinding of flint in a stone crusher Here the alternative to exhaust ventilation is a water or steam spray which seems to run counter to the view expressed at the international conference held at Johannesburg in 1930 that for the prevention of dust a combination of methods should be applied—exhaust draught *and* the use of water In general as for instance in the recommendation to allow vacuum cleaning to be carried out during working hours the code is on common sense lines

The annual meeting of the Canadian Medical Association will be held in Toronto from June 20th to 24th under the presidency of Professor Alexander Primrose, C B, F R C S who has lately retired from his academic offices in the University of Toronto after many years of most distinguished service

THE WELFARE OF THE BLIND AND NATIONAL ECONOMY

BY

J. MYLES BICKERTON, F.R.C.S.

OPHTHALMIC SURGEON, ST. MARY'S COLLEGE HOSPITAL

The prevention of blindness is an economy on the part of the State because many blind persons eventually become burdens on the public. Ophthalmic surgeons and others can do an enormous service to the State by recommending methods for obtaining a complete and true register of the blind population and until this is in existence we are heavily handicapped in our efforts to reduce the incidence of blindness.

To-day there are only 52,727 persons on the Blind Register (1929) in Great Britain and there has been an increase of 26,887 in ten years—that is an increase of over seven a day—but this figure is by no means a true register of our blind population. The following groups of persons are largely overlooked and may increase the above figure to 250,000 blind persons:

1. Almost all blind persons of the well-to-do classes.

2. Infants below school age.

3. Those persons who become blind after leaving school at 14 years or after until reaching blind pension age at 50 years. Many of these persons refuse to be certified and regard it as rather a disgrace.

4. Those persons who become blind after 65 years of age and are not registered. They obtain the old age pension which is the same in amount as the blind pension—10s. weekly. This is a very large group and may increase as the average age of life increases.

5. Many blind persons of suitable age to obtain the blind pension between the ages of 50 and 65 years do not apply for it because they have never heard about it.

6. It is possible that there are even one million persons who are blind in one eye in Great Britain to-day.

CERTIFICATION OF THE BLIND

The certification of the blind is performed in a very haphazard manner in this country to-day in most places. In fact the definition of blindness is not always fully understood by those signing the certificates and in spite of the fact that the examination for these certificates may take a considerable amount of time they are often obtained in the busy out-patient departments of the voluntary or other hospitals. The blind persons have to wait about in the out-patient departments they have to bring an attendant or friend and frequently have to travel long distances. This is most objectionable and is wasteful of time, energy and money. The certification can be arranged by an examination at the County Hall, London, but the voluntary blind societies often find that a long wait is necessary before even an examination takes place.

Certain provincial centres are far ahead of London in this respect. Glasgow, Liverpool, Sheffield for example—and at these places special surgeons make the examinations in private or at clinics for which a fee is paid. Detailed records are taken under a uniform system which is in most other places very few particulars are asked for or given. In Glasgow an index card register is made after the manner of the census where by means of holes punched in these cards a careful register of cessation age, direction is kept. By putting these cards through a sorting machine very valuable data may be had in a minimum of time. The writer understands that the whole census of blind may shortly be dealt with under this scheme, the funds for which are provided from three sources: (1) large Government grants; (2) local authorities and boards of guardians; (3) charitable organizations—the voluntary blind societies.

The British Medical Association has stated that it is not the duty of the surgeons of the voluntary hospitals to sign blind certificates and it considers that a fee of one guinea is a reasonable charge for this important work. When it is realized that some examinations might take from half to one hour (as fields of vision might require to be taken and important details as to causation etc. noted for the register) a guinea fee is no exorbitant. Indeed in some places a fee of two guineas is now being paid. In Glasgow the guinea fee is divided between two doctors who make separate examinations and so share the responsibility, and in addition bed-ridden persons are visited in their homes at an agreed charge. This is intricate and difficult work and requires an experienced surgeon. It is much better to employ a few surgeons who are familiar with all sides of this work, and in this way only can uniform and reliable records be obtained for registration purposes.

CONCLUSIONS

1. The present register of the blind population is totally inadequate and the true figure might be even 250,000; also valuable data are not available under the present system.

2. The recommendations of the Council of Ophthalmologists (printed below) should be carried out.

3. The voluntary blind societies should pay a fee for the certification of the blind which certification could be done by an examination (*a*) at a clinic at an eye hospital, (*b*) in private, (*c*) at a clinic at certain other hospitals, (*d*) at the home of a bed-ridden person.

4. Could not the Advisory Committee on the Welfare of the Blind recommend that steps be taken immediately by the Minister of Health to bring the whole blind population under review? In order to do this it might be necessary to make blindness a certifiable or notifiable disability, or possibly the same object could be realized by increasing the blind pension in comparison with the old age pension.

5. If such a register of the blind as is outlined above were in existence the following benefits could be obtained: (*a*) more active steps could be taken by ophthalmologists to combat the scourge of blindness; (*b*) the benefits (or the reverse) of sight-testing opticians could be viewed in their proper perspective; (*c*) the huge blind figures would enable the eye hospitals to obtain the funds which are urgently needed to carry on the work of the prevention of blindness; (*d*) the data might have eugenic value.

RECOMMENDATIONS BY THE COUNCIL OF BRITISH OPHTHALMOLOGISTS

The subcommittee of the Council of British Ophthalmologists on the certification of blind persons has expressed the following opinions in its report:

1. Except in certain localities certification of the blind is done in a haphazard manner and there is a lack of uniformity both in the method of certification and in the selection of the diseases certified as the cause of blindness. In addition to this a large number of the applicants require very careful examination by a competent [illegible] before [illegible]

2. A complete and uniform record of the blind [illegible] of the United Kingdom compiled periodically [illegible] and would be an important [illegible] in addition to regular information as to the number [illegible]

3. Reports from Liverpool, Glasgow and Leicester show that in the present complete absence of system, [illegible]

numbers of persons are certified as blind and thereby are placed in a position to draw pensions and other advantages from public and charitable funds who are not entitled to such benefits while others of the blind population never come under observation at all Any extra cases which may at present exist are therefore quite immaterial

4 A system under which the entire blind population comes under review needs to be established and steps should be taken to ensure that it be of universal application

5 The system of clinics which has now been working for two years in Glasgow has proved its efficiency and meets with the warm approval of the committee and on one such basis under clinic should be established in all large centres of population

6 The system adopted should also be available for use in isolated areas by ophthalmic surgeons recognized for the purpose of certification Such surgeons should have power to refer doubtful cases to the nearest clinic

7 The determination of the suitability of children of school age for special forms of education and of applicants for technical training under the Blind Persons Act should be a function of the organization working the system

8 Certificates of blindness except such as are granted by ophthalmic surgeons working the system should not be accepted by public authorities or by charitable agencies

9 If such a scheme as is contemplated above can be adopted the cases of blindness will be duly ascertained and recorded on a uniform basis for the whole Dominion and statistics of the most varied character will be available in a way unequalled by any other nation

MEDICAL RESEARCH COUNCIL

ROCKEFELLER MEDICAL FELLOWSHIPS

The Rockefeller Medical Fellowships for the academic year 1932 33 will shortly be awarded by the Medical Research Council and applications should be lodged with the Council not later than June 1st 1932

These Fellowships are provided from a fund with which the Medical Research Council has been entrusted by the Rockefeller Foundation Fellowships are awarded by the Council in accordance with the desire of the Foundation to graduates who have had some training in research work in the primary sciences of medicine or in clinical medicine or surgery and are likely to profit by a period of work at a university or other chosen centre in the United States before taking up positions for higher teaching or research in the British Isles In special circumstances the Fellowships may be tenable at centres of research not in America

A Fellowship held in America will have the value of not less than £350 a year for a single Fellow with extra allowance for a married Fellow payable monthly in advance Travelling expenses and some other allowances will be paid in addition Full particulars and forms of application are obtainable from the secretary Medical Research Council 38 Old Queen Street Westminster S W 1

DOROTHY TEMPLE CROSS RESEARCH FELLOWSHIPS IN TUBERCULOSIS

The Dorothy Temple Cross Research Fellowships in Tuberculosis for the academic year 1932 33 will shortly be awarded by the Medical Research Council and applications should be lodged with the Council not later than June 1st 1932

The object of these Fellowships as defined in the trust deed is to give special opportunities for study and research to persons intending to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis in all or any of its forms Candidates must be British subjects and must possess suitable medical veterinary or scientific qualifications They must also be able to produce satisfactory evidence of their ability to make good use of the opportunities offered by the Fellowships

The Fellowship will preferably be awarded to candidates who wish to make their studies or inquiries outside the borders of Great Britain They will be awarded for one year as a rule but in special cases may be renewed The value of the Fellowships awarded will depend in each case upon the standing and qualifications of the candidate but will not be less than £450 per annum payable monthly in advance Travelling and some incidental expenses will be paid in addition It may also be possible to award a Senior Fellowship of considerably greater value to a specially well qualified candidate wishing to undertake an intensive study of some particular problem of tuberculosis at a chosen centre of work in another country

Further particulars and forms of application are obtainable from the secretary of the Medical Research Council

TREATMENT OF CANCER

MINISTRY OF HEALTH'S CIRCULAR

In a memorandum issued to-day (Circular 1276) the Ministry of Health invites the attention of local authorities to measures which may facilitate the treatment of cancer patients and emphasizes the wider provision for radiological treatment now available as a result of the work of the National Radium Trust and of the Radium Commission The facilities provided by the latter organizations are distributed all over Great Britain The Radium Commission decided from the outset to concentrate radium therapy at certain hospital centres nominated by the medical faculty of the local university and has secured the establishment of national centres in provincial voluntary hospitals at Birmingham Bristol Leeds Liverpool Manchester Newcastle on Tyne Sheffield and Cardiff It is now thought that as these centres are somewhat unevenly distributed there is need for a number of smaller regional centres in the East Anglian and South Western districts As part of their agreements with the Radium Commission for loans of radium the hospitals mentioned undertake to organize the radium to the maximum practicable advantage of patients to set aside as many beds for patients undergoing treatment as will keep the radium fully employed to treat suitable patients coming from any sources (including rate aided institutions) and to keep full records of cases Owing to varying factors such as distance of area from a convenient centre facilities for consultation transport of patients etc it is impossible to lay down rules for general application as to the arrangements which local authorities should make for the fullest benefit of the inhabitants of their areas It is however recommended that the local authority should fix upon the hospital where a conveniently situated radium centre is established and make arrangements for the residents in the area to obtain radium treatment in that centre whenever necessary

As regards cancer cases in general it should states the memorandum, be realized that adequate treatment requires all the resources of a hospital with modern equipment It may thus be necessary for local authorities to provide for the removal of patients from a less to a more fully equipped hospital A scheme of cancer inquiry such as that outlined in Circular 1136 is of advantage in this respect because it provides a suitable means of deciding how the needs of patients in any particular area can best be met Attention is also drawn to the provision in the normal course of health service of facilities which incidentally help in the prevention detection and early treatment of cancer Maternity and child welfare venereal disease, and tuberculosis services are valuable in the prevention of cancer by securing treatment for conditions which may favour its onset for the adequate care of women in childbirth may help to prevent later occurrence of uterine cancer the effective treatment of syphilis may be of value in the prophylaxis of cancer of the tongue while the effective treatment of lupus and of scrofuloderma may prevent the subsequent appearance of cancer

THE TYPE OF STOMACH PREDISPOSING TO DUODENAL ULCER

SIR,—In considering the pathogenesis of duodenal ulcer it is desirable to ascertain whether there is a special type of stomach which as I first suggested in 1922 predisposes to its development. In this connexion I have read Dr. Seward Morley's paper on duodenal ulcer in your issue of April 9th with much interest. No definite conclusion can be drawn from investigating the type of stomach which is present when its secretory and motor functions have been profoundly modified as a result of the associated gastritis and of the disturbance in the activity of the pyloric sphincter which results from the presence of an ulcer in its immediate neighbourhood. Dr. Morley does not say when his test meals were given and x-ray examinations made, but I presume that the investigations were carried out before and not after treatment.

In April 1929 Dr. J. F. Venables and I published a paper in the *Guy's Hospital Reports* entitled "The true incidence of hypochlorhydria in gastric and duodenal ulcer," in which we showed that the curve of acidity obtained with a fractional test meal was almost constantly higher after successful medical treatment of a gastric or duodenal ulcer than before, owing, presumably, to the disappearance of the gastritis with which ulcers are always associated. Thus one hypochlorhydria with a test meal similar to that in Dr. Morley's Chart IV became a high normal and one became an extreme hyperchlorhydria (Fig. 1); two low normals became high normal, one remained borderline high normal and one became hyperchlorhydria; even high normals became hyperchlorhydria and one remained unaltered; eight hyperchlorhydrias became small to moderate and four remained unaltered (Fig. 2).

Though I have no accurate statistics on the subject I believe that a similar change frequently takes place in the shape of the stomach when the delayed evacuation and dilatation and contraction round the ulcer and spasm or relaxation of the pyloric sphincter disappears as a result of treatment. This such delay is frequently present is shown by the fact that an average three hour residue of 57 c.cm. was present in Dr. Morley's 250 cases. The fact remains, however, that Dr. Morley's investigations support the view that a hyperchlorhydric type of stomach with a relatively low curve of acidity with which it was associated. Dr. Morley's series to a higher one. Our observations show that a short high rapid (empty in 3 hours) stomach with hyperchlorhydria is generally present in the duodenal ulcer which may give rise to precisely similar symptoms to those of duodenal ulcer though no deformity is seen with the x-rays and inflammation without ulceration is found if an operation is performed in most early cases of duodenal ulcer and in patients who have recovered from an ulcer as a result of medical or surgical treatment.

(a) (b)

FIG. 1.—Duodenal ulcer with chronic gastritis. (a) July 20th 1928. (b) March 6th (about August 15th) 1928. After 6 months treatment. (Patient symptomless, duodenal ulcer healed, hyperchlorhydria unaltered.)

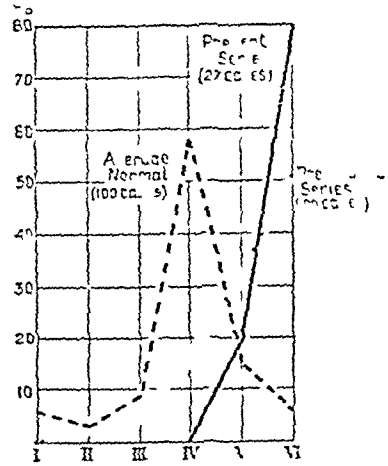

FIG. 2.—Types of test meal in 100 cases of duodenal ulcer before treatment and 27 after treatment compared with 100 normal cases. (I. Achlorhydria. II. Hypochlorhydria. III. Low normal. IV. Average normal. V. High normal. VI. Hyperchlorhydria.)

The evidence is strong that this hyperthenic stomach is an essential or almost essential predisposing cause of duodenal ulcer.—I am, etc.,

April 18th ARTHUR F. HURST

POLYCYTHAEMIA RUBRA AND ACHLORHYDRIA

SIR,—Dr. Robert Platt in the *Journal* of April 2nd records the case of a man aged 47 with typical erythraemia—polycythaemia rubra with splenomegaly—who after giving blood for blood transfusion on three occasions developed anaemia with low colour index and then by fractional examination of the gastric content he was found to have complete achlorhydria at the Clinical Section of the Royal Society of Medicine on October 9th 1931 (*Proceedings*, p. 10). I demonstrated the case of a woman aged 42 who had had typical erythraemia rubra with splenomegaly before the occurrence of two attacks of extremely severe haemorrhage in autumn more than seven months after the first case of haematemesis. Her haemoglobin was 95 per cent. though her erythrocyte count had risen to 9,000,000 per c.mm. Fractional examination of her gastric contents showed that she had complete achlorhydria even after subcutaneous injection of histamine.

The finding of complete achlorhydria in cases of erythraemia after much loss of blood is in keeping with repeated blood transfusions during the anaemic phase with the return of achlorhydria to anaemias of various types—especially simple achlorhydric anaemia and pernicious anaemia. It is interesting that [illegible] woman though still anaemic [illegible] 2 days after free hydrochloric acid [illegible]

I identify [illegible] success I have had [illegible] with erythraemia in which early [illegible] but no histamine examinations [illegible]

aged 52 under the care of the late Professor G A Gibson of Edinburgh whose case was recorded by Watson Wemyss in the *Edinburgh Medical Journal* (1911, vi 125) —I am etc

London W 1 April 21st I PARKES WEBER

MALIGNANT DISEASE OF PHARYNX AND LARYNX

SIR—My object in writing is to voice a straightout personal opinion on the very vexed question of the treatment of cancerous growths of the pharynx and larynx while freely acknowledging the very genuinely held diverse views not only in different countries but even by colleagues in the same hospitals In the course of thirty years experience the principal methods employed in the attempted eradication of this devastating growth in these areas have been the surgical knife diathermy *x* rays and radium intermixed with various stunts of very limited duration A symbiosis my own experience with the seen work of various colleagues the heard results of worthy investigators and the effects of close inquiries in various visited countries the following opinions have been arrived at and will be put bluntly before elucidation

1 In all cases of buccal tonsillar or palatal infection the diathermy knife is strongly indicated and provided that the growth does not extend below the posterior pillar of the fauces gives a very excellent chance of cure

2 In early intrinsic laryngeal carcinoma the surgical knife is best employed either by way of a window resection in one of the walls of the thyroid cartilage or by a median thyrotomy and should give an equally hopeful prognosis

3 Pharyngeal and extrinsic laryngeal involvement has generally advanced to a grave extent before it has set the patient sufficient trouble to seek medical advice and therefore together with late intrinsic never enables the surgeon to give any sort of hopeful prognosis by means of any of the present known methods

In dealing with the first group it is obvious that diathermy rather than the ordinary knife is the only possible surgical means of completely removing the deeply invading growth about the tonsils and the adjacent bony areas A second sitting being often necessary to complete the removal When cervical glands are involved and it has been decided to remove them this should be done at a preliminary operation owing to the dense fibrous scars left by the diathermy wound Should no glands be felt it is strongly advisable that the patient after operation should undergo a course of deep *x* rays Inoperable glands can be treated by the insertion of radium needles or deep *x* rays the result guiding the operator as to whether it is justifiable to attack the primary growth Radium will be dealt with under the third heading

Intrinsic carcinoma occurs much less frequently than the extrinsic and surgical methods are the only ones that need be considered in the early infection which is usually on or in the immediate neighbourhood of one of the vocal cords The window resection I prefer for the following reasons

1 It can be performed more quickly and so lessens the amount of anæsthesia the loss of the patient's resistance and the chance of pneumonia

2 The preliminary tracheotomy which though not absolutely necessary is advisable can be more quickly abandoned (one to two days as a rule)

3 If made freely enough it gives as good a view into the larynx and allows of as ready a removal of the infected area

4 It does not interfere with the movements of the larynx and so enables any phlegm to be coughed up thereby lessening the liability to pneumonia

5 The shorter convalescence (*The last two cases were* out of hospital in fourteen days)

The third group includes the so called inoperable cases and those where only a very extensive operation such as a complete laryngotomy will suffice Taking the latter first it is an openly disputed point whether these operations are ever justifiable the objectors holding that even with the best result possible it is extremely doubtful whether the individual will ever be of any value to himself his family or his State Certainly it should never be attempted by anyone not extra specially experienced in this area and should be performed on a subject who age physical fitness and past history render him or her a suitable subject beyond all doubt

The inoperable group leads us to the very vexed question as to the value of radium and *x* rays in the treatment of this dire condition At first *x* rays were found to be of little if any real value not even for alleviation but with the advance of knowledge and improvement in apparatus the modern deep *x* ray has become of very great value both by itself and in conjunction with surgical measures Radium has been left to the last because although it had such a *popular heralding* its use has become more and more disappointing in these areas Every known method has been carefully studied and tried and because of the published results by certain investigators has been most thoroughly persevered with only to end in great disappointment These remarks of course refer only to carcinomata of the throat and larynx and it is with the greatest regret and diffidence that the statement is here made that with the present known methods the use of radium in the treatment of carcinoma in the above area is of little value This finding has been arrived at by personal experience backed by that of valued colleagues and opinions expressed by investigators abroad particularly on the other side of the Atlantic It is earnestly to be hoped that radium as in the case of *x* rays will increase in its remedial value in the course of time and that while no research is spared in curative efforts the prevention of this fatal disease will be equally sought after

While on the subject of laryngeal carcinoma it is only fair to stress the difficulties which the specialist encounters in most hospitals where only a handful of beds is allotted to the whole specialty of ear nose and throat A surgeon who is also a conscientious citizen is therefore forced to think very seriously whether he is justified in occupying a bed for so long in order to place an almost certainly inefficient person back on to the hands of an overburdened State rather than help a number of younger people back to their jobs and also perhaps prevent them by the very removal of some exciting cause from being ultimately the victim of this dreaded scourge —I am etc,

FRANCIS MUECKE CBE FRCS

London W April 20th

BLADDER HEALING AFTER SUPRAPUBIC CYSTOTOMY

SIR—I have read with considerable interest the article on bladder healing after suprapubic cystotomy by Mr James B Macalpine in your issue of February 6th and sincerely agree with his remarks concerning bladder sepsis

While one is in complete agreement with the thesis that it is wellnigh impossible to secure a watertight joint by *closing* a vesical wound around a tube—that is to say placing a tube in one portion and drawing together the remainder of the wound by interrupted stitches —yet a drainage tube may be inserted into the bladder between the primary wound and the apex through a separate stab wound whose margins are subsequently inverted by a purse string suture Careful apposition of the margin of the primary vesical wound can then be secured with the formation of a temporary watertight system

Although Mr Macalpin states that the only particular in which the suprapubic wound differs from any other surgical wound is contamination with urine he omitted to qualify his statement by adding that in the vast majority of cases this urine is infected For the milder degrees of sepsis careful and copious pre operative irrigation of the bladder may suffice but for the severer grades a two stage prostatectomy with continuous irrigation through a Macalpine's combined drainage and irrigation tube is advisable Cellulitis in the cavum Retzii would appear to depend mainly upon three factors first inoculation of the contained cellular tissue with septic urine during the performance of prostatectomy secondly non obliteration of dead spaces in the retropubic space and thirdly strangulation of the tissues by over tight suturing After suprapubic prostatectomy there is a tendency for stagnant urine blood etc to collect in the prostatic cavity and become infected One therefore questions the wisdom of employing an indwelling or in lying catheter which would appear to be the causal factor of the undue prevalence of post-operative epididymo orchitis recorded in the Old Country The following is the post operative technique adopted at the New South Wales Community Hospital

After the toilet of the bladder is completed the prostatic cavity is packed with a sausage roll the free end of which is brought through the lumen of a small Lane's tube (1 2 to 3 4 inch diameter) through a stab wound in the anterior abdominal wall The distal end of the Lane's tube is attached to a suitable length of rubber catheter (or other rubber tubing) of an appropriate calibre which is attached at the side of the bed The sausage roll is then withdrawn and the Lane's tube is replaced The abdominal wound is closed in layers with the exception of the stab wound for the Lane's tube and a pressure dressing applied permitting accurate apposition of the redundant vesical mucous membrane

The sausage roll is then withdrawn by the rubber tubing which is discontinued and a third layer of packing with iodoform and a fresh piece of gauze packing attached having inserted through its wall a short length of glass tubing which extends down through the centre of the packing to the bladder and which is attached by continuous irrigation of normal saline solution from a reservoir of mercury suspended above the bed The rubber tubing which connects the glass tube to the bladder with lubricant is then withdrawn and the glass tube is replaced by a Malpine tube which is connected to the continuous irrigation until the end of the second week On the removal of the Malpine tube the suprapubic wound heals by granulation and until the suprapubic wound heals the bladder is irrigated once or twice daily with normal saline solution

The above mentioned method not only enables the patient to be kept dry and comfortable but greatly reduces the arduous duties of the attendant nurses The transverse skin incision heals by first intention while the tube track through the base of the upper flap is usually sealed by the beginning of the fourth week—I am etc

EDUCATION FOR MARRIAGE

SIR—Mr Kenneth Walker's letter has done nothing to clear up the [illegible] be is raised by me in your issue of April 9th Here words as incorrect my interpretation of Mrs Neville Rolfe's intentions of the question of contraceptive advice at her proposed bureau It is only necessary to refer to Mrs Rolfe's statement that it does not appear to me that the question of birth control is to be [illegible] to [illegible] to [illegible] to

if the patient has had a preliminary injection of morphine and atropine but under every circumstance the patient must be led and not upperc t into a stage of surgical anæsthesia The chloroform mask should never be brought into close contact with the face and after the patient has been dulled under the chloroform vapour ether should always be added The correct administration of any general anæsthetic is not anæsthetic coma but anæsthetic sleep attained by the administration of chloroform and ether plus premedication —I am etc

M r rie M r h R W HOLMBROOK

LCC PATHOLOGICAL SERVICES

SIR —May I in a final letter restate my thesis which has been consistently misrepresented by my critics and which is that when Parliament by its Local Government Act of 1929 handed over the Poor Law hospitals to the county councils it enjoined upon them the duty of avoiding wasteful duplication of already existing facilities at the voluntary hospitals and elsewhere I maintained that the provision of the elaborate and expensive group laboratories which the recent report of the London County Council declared are now being built is a wasteful duplication of existing laboratories That opinion was categorically confirmed by the letter from the chairman and secretary respectively of the Voluntary Hospitals Committee the statutory authority which the Act required the London County Council to consult The opinion of that body must carry more weight than the opinions of Dr Goodhart and Dr Kelson Ford neither of whom can claim to be personally disinterested in this matter Dr Goodhart's argument born of irrelevancies is (1) that these facilities do not exist —a mere travesty of fact (2) that the voluntary hospitals which have hitherto done the pathological work for the county hospitals never did that work properly Dr Goodhart's charge that the LCC cannot be too pleased at his wholesale condemnation of services which they themselves have commanded His statement has been amply rebutted in the case of St John's Hospital Lewisham in a letter in your issue of April 16th and the charge is equally untrue regarding St Mary's Hospital Incidentally I may say that I softened Dr Goodhart's indictment with respect to St Mary's Hospital from never properly to indifferently He expresses himself as being aggrieved by this substitution and I now restore never properly for indifferently as his actual charge Dr Goodhart's predilection for municipal management is such that on his own showing he forsook a more profitable appointment at a voluntary hospital for a less profitable post at a municipal hospital although filial feeling and inherited tradition should have kept him in the voluntary fold

Dr Kelson Ford gleefully thinks that Dr Meredith Richards has floored me by his letter in the *Times* in reply to mine I did not answer Dr Meredith Richards in the *Times* because I was waiting for a more authoritative reply to my letter from responsible persons at the London County Council which has not yet been forthcoming The answer to Dr Meredith Richards and to Dr Kelson Ford is however quite easy Taking their own figures as correct the 6 000 beds in the London teaching hospitals are predominantly filled with acute or difficult cases requiring laboratory investigation the 17 000 beds in the London County Council general hospitals are as a perusal of the recent report demonstrates predominantly filled with chronic cases—for example of disablement from accident old age mental deficiency and other incurable conditions presenting no difficulty of diagnosis and not calling for laboratory investigation But the cardinal difference of course is that none of the laboratories of the voluntary hospitals are charged upon the rates, as are the laboratories at the county hospitals Moreover one of the principal functions which the laboratories of the teaching hospitals fulfil is the training of students and the prosecution of research needs which justify a certain fullness of equipment, and in several instances the pathological laboratories at the voluntary hospitals have been furnished by large subscriptions from rich men who can like Sir Anthony Gloster pay for their fancies and are not answerable to impoverished rate payers irate at seeing their money misspent

But if as seems to be the contention chiefly relied upon by Dr Goodhart and Dr Kelson Ford the existing laboratories are insufficient for the discharge of the new work it is surely more sensible to expand them as may prove necessary than to build completely new ones The debates in Parliament just concluded upon the Budget clearly demonstrate the desperate need for economy in the public services neglect of quite obvious occasions of economy by public bodies is peculiarly indefensible at the present time —I am etc

TREATMENT OF OSTEO ARTHRITIS OF THE HIP

SIR —Dr Hermaman John on is correct in assuming that at the recent discussion at the Medical Society of London I referred to those cases of arthritis of the hip which had failed to benefit by simple routine medical lines of treatment In such cases surgical intervention is absolutely essential —I am etc

London W April 26th B WHITCHURCH HOWELL

A PHARMACEUTICAL CENTENARY

The firm of C J Hewlett and Son Ltd wholesale druggist which was founded in 1832 gathered its friends and staff to a centenary dinner at the Abercorn Rooms London on April 23rd A number of people prominent in pharmacy pharmaceutical education and organizations serving the drug trade were present together with a representation of the medical and veterinary professions Dr Alfred Cox Medical Secretary of the British Medical Association in proposing the toast of the evening mentioned that he had known the firm since 1887 and that he owed not a little in the difficult days when he began practice to John Hewlett the son of the founder of the firm The House of Hewlett he said exhibited some characteristics which he liked to think of as peculiarly British the rise to considerable things from small beginnings the family element in the direction and in relations with the staff the combination of solidity and carefulness with a desire for progress and finally the care for a reputation free from blemish or aspersion The name was associated in his mind with elegant pharmacy The firm was one of the first to take a pride in the appearance of its goods so that the look of its wares appealed to the best type of family doctor In the speaker's own early experience of practice drugs were anything but elegant They justified the remark of Montaigne who begged his doctors not to give him medicine until he was better able to stand it The toast was also spoken to by Mr A R Melhuish president of the Pharmaceutical Society who mentioned that Mr Charles Hewlett the founder of the firm was one of the first members of that body in 1841 Mr Vivian C Hewlett the present head referred modestly to the traditions of his firm but forbore from giving any outline of its history which is being incorporated in a booklet Mr E J Millard another director also responded saying that the firm was celebrating its centenary in a spirit of mingled pride and gratitude

Obituary

SIR W WATSON CHEYNE BT KCMG, CB FRS FRCS

Past President Royal College of Surgeons of England Consulting Surgeon King's College Hospital

As briefly announced in last week's *Journal* Sir Watson Cheyne died on April 19th in his eightieth year This distinguished King's man was the chief link between the new hospital and the old between present day surgery and the great Lister and between the medical schools of London and Edinburgh

William Watson Cheyne was born in the little village of Fetlar in the far away Shetland Islands on December 14th 1852 He came of seafaring stock and there can be little doubt that Scandinavian blood ran freely in his veins The appearance of this was suggestive in earlier days when his honey coloured hair and fair pointed beard had a decided Viking look His descent from Norsemen is also shown in his life long love for the sea It is curious to note that he was anxious to go to sea as a boy but circumstances were against it and yet towards the end of a long public career he wore the uniform and carried the rank of a rear admiral in the Royal Navy His parents died in his childhood and he was brought up by a devoted grandfather the minister at Fetlar and so Cheyne was one of the many thousands of sons of the manse who have made good in the British Empire This clergyman passing rich on £200 a year must have denied himself many things to have given the good education he supplied to young kinsmen But then respect for education and a love of learning are imbred in the Scottish character

From Shetland Cheyne was sent across the sea to the Grammar School in Aberdeen After two years there he entered King's College Aberdeen where he studied from the age of 14 to 17 During these years he still longed for the sea but this had to be given up as his family could not afford it In fact he drifted into medicine with the vague idea that he might be able to take up a seafaring career as a ship surgeon At the age of 17 he went to Edinburgh to begin the study of medicine but delicate health prevented him from doing more than work at chemistry for the first winter This delicacy was a threatening of tubercle and he was never strong enough to indulge in the violent sports and games of youth Possibly this deprivation of social opportunities accounted for the extreme shyness which always was his greatest handicap in life He felt this handicap keenly realizing that his diffidence and shyness had often been mistaken for exclusiveness or bearishness Those who knew Cheyne chiefly as a practical surgeon may not realize that he was so devoted to chemistry that not only did he get the first prize amongst the many students at the University of Edinburgh but that he worked for a second year at chemical science and again won the prize Indeed he looked forward to winning the Hope Scholarship but unfortunately it was abolished as he just came due for it In this second year he took the three medals for anatomy physiology and chemistry During his residence at Edinburgh he gained in all twelve medals In his second full year he took up surgery physiology and practical anatomy These classes left him free from 12 to 1 and although not a dresser he more or less accidentally drifted into Lister's classroom to pass the time He was from the first fascinated by Lister's teaching and by the Master's interest in the chemistry of antiseptics Cheyne took full notes of these lectures during the winter of 1872–73 and these notes are now deposited in the library of the Royal College of Surgeons Such an industrious student was Cheyne that he used to sit up all night before an examination going over his work The examination for the physiology and Lister classes took place on the same day He was particularly anxious to beat the physiology man who had already won twice Cheyne tied with his opponent getting 99 per cent of the marks in the afternoon he sat for the examination for Lister's prize and although opposed by men in the fourth and fifth year he obtained 96 per cent of full mark Lister was so struck with this performance of a junior that he asked Cheyne why he had never applied for a dresserships Needless to say Cheyne applied at once and was selected out of a class of between 200 and 300

Cheyne graduated M B C M with first class honours in 1875 and Lister promptly invited him to become house-surgeon Unfortunately there was no house surgeonship vacant for a year nor was there any other resident post in which he could pass the time About that date there were rumours of the birth of a new science of bacteriology in Germany and Cheyne turned his attention to the Continent But how was he to get there without means? He had recently inherited a small legacy which realized £150 and with this modest sum he spent a year in study on the other side of the Rhine On his return to Edinburgh he started some bacteriological experiments and was successful in winning the Syme Bacteriological Scholarship which brought him in £100 a year for two years

How did it happen that Cheyne came to London? One spring morning in 1877 he was asleep in his lodging and woke to find Mr Lister beside his bed with the news that he (Lister) had been invited to come as surgeon to King's College Hospital that he had agreed to go on condition that he might bring his own resident and dressers and that he wanted Cheyne to be his first house surgeon in London At the old King's College Hospital Cheyne started as house surgeon during the winter of 1877–78 taking with him three other Edinburgh graduates As clinical clerk there was Dr John Stewart a devoted disciple of the Master of whom he has written several touching pen pictures Dr Stewart succeeded Cheyne as house surgeon during the great war he served with the Canadian Army in France and after-

wards returned to his practice in Halifax Nova Scotia The two dressers who came with the Edinburgh contingent were James Altham and W H Dobie The former has died the latter is still in leading practice at Chester Dr Stewart has told the writer of this memoir that the only awkwardness he felt in coming to King was that he and Cheyne were both bearded while his English colleagues were spruce shaven The colleagues—of whom Colonel Richard P Bond R A M C is possibly the only survivor—welcomed the Scottish *invasion quite cordially and* the only opposition Lister and his suite had to put up with came from the Sisters of St John to whom the nursing was in those days farmed out The ladies looked upon surgery as the handmaid of nursing and the high church ritual to which they were devoted and they opposed all sorts of difficulties to the careful measures and personal details which the then novel method of antiseptic dressing demanded

When his period of office as house surgeon was over, Cheyne had to begin the struggle for a practice and his daily bread So hopeless was this that at one time while working at his bacteriological researches he meditated trying to enter the Indian Medical Service which *in those days offered promising careers of rapid* success However Lister gave him a retaining fee of £200 a year to administer chloroform and set with Sir Rickman Godlee as his assistant in private practice Needless to remind readers that Godlee was Listers nephew and wrote the delightful life of his uncle which should form part of the library of every medical man The two young surgeons Cheyne and Godlee struggled along from the small beginning of £200 a year until each of them became in his turn President of the Royal College of Surgeons of England

From these early struggles to the present day Cheynes career is known to the world His researches the books he wrote the practice he conducted the students he taught the *honours he attained are known to all* His long career in the public eye culminated as I have already said in his work with the Grand Fleet during the war and in his wearing as admiral that uniform which he had thirsted after in his early days in Shetland Had his health permitted he would doubtless have continued to serve his profession and his country *in the House of* Commons The last active years of his life were largely devoted to sailing on his beloved ocean round his native island The wheel had come full circle STC T

This personal memoir signed with familiar initials brings Sir Watson Cheyne *before our readers eyes* To make the record more complete we add some further biographical details

In 1879 while acting as surgical registrar at Kings College Hospital with charge of patients in Listers wards Cheyne took the I R C S diploma thus beginning his long connexion with the Royal College of Surgeons of England which culminated in the Presidency from 1914 to 1916 In 1880 he won the Jacksonian prize for his dissertation on the history principles practice and results of antiseptic surgery He was Hunterian professor in 1888 [illegible] in the three following years Bradshaw lecturer 1898 and Hunterian Orator in 1915 From his own figures he was a member of the Council and from teaching hospital *a member of the Court of Examiners* The difficult case [illegible]d him by the College was in 1924 when he 17 000 beds [illegible] the Lister medal in recognition of distin pitals are as [illegible]utions to surgical science and delivered predominantly Memorial Lecture entitled Lister the disablement fro[illegible] surgeon and other incu[illegible]e Hospital he became assistant surgeon of diagnosis and [illegible] his retirement from the posts of full But the cardinal surgeon and professor of clinical surgery he was appointed consulting surgeon and professor emeritus He was elected F R S in 1894 During the South African war he served as civil consulting surgeon to the Forces and received the C B He was created a baronet in 1908 on appointment as Surgeon in Ordinary to King Edward VII For his services with the Navy during the great war he was created K C M G in 1916 On retirement from practice in the following year he was elected M P for the Universities of Edinburgh and St Andrews and from *1918 to 1922* represented the combined Scottish Universities From 1919 to 1930 he was Lord Lieutenant of Orkney and Shetland Sir Watson Cheynes academic honours included the H D of Edinburgh the D Sc of Oxford and honorary Fellowship of the Royal College of Physicians and the Royal College of Surgeons of Edinburgh His principal publications were *Antiseptic Surgery* (embodying the Jacksonian essay) a *Manual of Surgical Treatment in seven volumes (jointly with Mr F F* Burghard) *Tuberculous Diseases of Bones and Joints* and a number of smaller books on the antiseptic treatment *of wounds and suppurative conditions*

A largely attended memorial service was held in the chapel of Kings College Hospital on the afternoon of April 25th Mr Wilfred Trotter F R S Serjeant Surgeon to the King represented His Majesty

---

Dr THOMAS DUFF of Roslin died on March 18th *He* was the son of Sir Benjamin Duff Bt and was educated at Blair Lodge School Polmont and the University of Edinburgh After obtaining the triple qualification of the Conjoint Board in Scotland in 1900 he practised for some years *in Cheshire* but then decided to take up mental work and was for some time an assistant medical officer at the Norfolk County Asylum under the late Sir David Thomson He later devoted his life to private mental cases *but nine* years ago returned to Scotland to the Midlothian and Peebles Mental Hospital where he was deputy medical superintendent

Medico-Legal

UNUSUAL CLAIM UNDER ASSURANCE POLICY ACCIDENT OR DISEASE

In the King's Bench Division before Mr Justice Roche on April 14th 15th and 19th an action was brought by Mrs Weyerhaeuser widow of Mr C A W Weyerhaeuser of St Paul Minnesota and his administrators against Mr Montague Evans an underwriter at Lloyds for $754 under a policy of assurance It was stated that the policy concerned claims amounting in all to about £83 000 in respect of which some premiums had been accepted by the defendant and other underwriters The policy provided that the legal representatives of Mr Weyerhaeuser should receive payment under it if within a year from January 15th 1930 he sustained bodily injury by accident which proved fatal within three months The policy did not cover death directly or indirectly caused or contributed to by disease or m[illegible] did it cover death directly or indirec[illegible] medical or surgical treatment It appe[illegible] the policy was taken out Mr Weyerhae[illegible] and a friend Miss Lee started on a [illegible] German steamship round the world [illegible] Mr Weyerhaeuser was troubled with a [illegible] in his nostril He had previously been [illegible] College [illegible] these had been dressed by Mrs Lee Miss [illegible] Edinburgh this pimple and it was alleged pressed squeezed and jabbed [illegible] Stewart it with an improvised *probe thus* accidentally causing a break *in the tissues* The plaintiff's case was that throu[illegible] succeeded break bacteria which would otherwise have remained on [illegible] war he skin or have been confined to the superficial tissue entered [illegible] and after- the blood stream Mr Weyerhaeuser was very ill on the day following this intervention by Miss Lee and although

He was treated by two doctors on the vessel he died six days later

Mr S L Porter K C who with Mr David Davies appeared for the plaintiffs contended that death followed an accident—that is to say the injury caused by Miss Lee when she tried to force out the pus by breaking down the walls of the pimple The word disease like the word accident was open to varying interpretations but counsel suggested that disease was something independent of accident which caused death If there was an injury from which fatal disease resulted the disease being part of the chain of causation that was death by injury and not death by disease The defendant who was represented by Mr Stuart Bevan K C and Mr Lennox McNair denied that Mr Weyerhaeuser sustained an accident within the meaning of the policy and claimed that his death resulted from natural cause or from disease within the exceptions to the policy—that is to say from an acute streptococcal or staphylococcal infection or both or from septicaemia or from pneumonia

In evidence for the plaintiffs Mrs Weyerhaeuser stated that her husband at the time was 63 years old and perfectly well indeed he was very robust Miss Lee described in the witness box how she treated the pimple she used a probe sterilized with alcohol The next morning the nose was much swollen but it did not occur to her that this was due to her interference Dr Hajo Jelden ship surgeon on the liner whose evidence was taken on commission stated that on being called to Mr Weyerhaeuser the day after this occurrence he found him suffering from inflammation of the upper lip His attention was not drawn to the condition in the nostril until the following day when it was pointed out to him by his fellow ship surgeon Dr Mudd In his opinion the cause of death was streptococcal infection in the blood Dr P V Panton (pathologist) expressed the view that the infection was staphylococcal He disagreed with the suggestion that the infection might get into the body by means of hair follicles or in other ways without abrasion

For the defence Sir Bernard Spilsbury gave evidence The common pimple he said resulted from an infection of the skin by staphylococci on full development it became a boil It was not necessary to have an abrasion for the micro organisms to gain entrance to the tissues many boils developed naturally without abrasion of the skin From the description he believed that Mr Weyerhaeuser was subject to acne and in his view an acne lesion was the most probable explanation of the development of the pimple in question Asked whether a pimple without such interference as was made by Miss Lee might cause death the witness replied that occasionally a pimple developed of itself and ended in death though this was very exceptional It was in a dangerous situation inside the nostril owing to the veins leading to the base of the brain The history of the case seemed to indicate that this was not an ordinary boil that the infection was not localized and that the resistance of the patient was inadequate He did not believe that the probing by Miss Lee would in itself have broken down the wall and sent infection into the tissues The probe had probably not affected the patient's condition one way or the other He agreed that medical practice was not uniform in dealing with such conditions and in any case any treatment was generally performed by the patient or his friends without medical assistance

Mr Warren Low also gave evidence for the defence

In closing the case for the plaintiffs counsel said that whether or not abrasion was required to cause the infection was purely a question of expert evidence There were two views one held by his witnesses and the other by Sir Bernard Spilsbury The court was not dealing with a scientific problem in the sense that it must eliminate every possibility but he maintained that there must be some abrasion to get a staphylococcal infection into the tissues If an abrasion was necessary then his submission was that the abrasion however small was an accident within the meaning of the policy

Judgement for the Defendant

Mr Justice Roche gave judgement for the defendant with costs He said that it was common ground that Mr Weyerhaeuser died from septicaemia due to the presence in his system of virulent staphylococci It was also common ground that the origin of the infection was the pimple in the nostril The plaintiffs case failed because there was no evidence that any accidental injury gave rise to the pimple Mr Weyerhaeuser was subject to pimples or carbuncles and there was nothing to show that this particular manifestation was due to the bite of any insect Its cause was in the realm of conjecture most probably it was acne He was not satisfied that Miss Lee had done any mischief by treating the pimple in the way she had done The *more probable* view was that expressed by Sir Bernard Spilsbury that what Miss Lee had done could not have caused the injury alleged—namely the driving of the infection which up to then had been superficial into the deeper tissues It appeared that the infection was already there and was getting worse when Miss Lee first saw the condition and that it forced its way through the resistance

In the judge's view Miss Lee had had nothing to do with the cause of death and therefore the plaintiffs had failed to make out their case

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT

The House of Commons this week discussed the Budget Resolutions altering taxation and the Estimates for Agriculture and India In the House of Lords debate arose on a Bill introduced by Lord Buckmaster to amend the law relating to motor car accidents

The Epsom College Bill was read a second time by the Commons on April 25th

Dr Fremantle presided at a meeting of the Parliamentary Medical Committee on April 26th Sir George Newman Chief Medical Officer of the Ministry of Health gave a survey of the main tendencies in the nation's health for the last fifty years and on the main lines of policy and administration followed by the Ministry of Health and by its predecessors He said he was amazed at the good health of the nation to day and gave reasons for the improvement including food leisure fresh air exercise and education A boy born in London to day had fifteen years more expectation of life than a boy born fifty years ago Leprosy cholera and plague were finished with as English diseases syphilis was checked tuberculosis was steadily declining and small pox completely held in check If the last disease became threatening the authorities had enormous reserves of doses of vaccine

Sir George Newman's address was interrupted by divisions of the House and he will confer again on a later date with the Parliamentary Medical Committee

Mr Baldwin announced on April 25th that owing to the illness of Mr Chamberlain the House of Commons would not discuss till next week the Order instituting the new import duties recently recommended by the Tariff Advisory Committee These duties are in force and include

	Additional Duties
Group X—Tartaric acid cream of tartar citric acid ammonium chloride	10 per cent
Formaldehyde whether in solution or polymerized menthol other than natural menthol	23⅓ per cent
Boric acid (refined) borax (refined) nitric acid anhydrous ammonia ammonium sulphate ammonium nitrate sodium nitrate sodium nitrite calcium chloride tin oxide zinc oxide	10 per cent
Group XVI—Toilet preparations including liquid preparations for dental purposes and mouth washes preparations for use on the hair face or body smelling salts	20 per cent

Exemptions for medical and surgical goods are specified in other sections as follows

Articles manufactured wholly or partly of the metals aluminium copper lead nickel tin zinc and alloys including any of these metals and parts of such articles (but not including scientific and medical instruments and parts thereof) additional duty 10 per cent

Cutlery Knives with one or more blades made wholly or partly of steel or iron (other than surgical knives) additional duty 10 per cent

Deaf and Mentally Defective Children Education

Replying to Mr Charles Edwards on April 21st Sir D Maclean said that on December 31st 1930 the latest date for which figures were available the number of children in England and Wales ascertained by school medical officers to be deaf was returned as 3121 of whom 1 915 were boys and 1 706 were girls The number of partially deaf children was 1 882 of whom 973 were boys and 909 were girls The period of compulsory education for deaf children was from 7 to 16 years of age Special schools for the totally deaf provided accommodation for 4 486 children and in addition there were 422 places in classes certified for the partially deaf It was estimated that the average cost of the education of deaf children was approximately £89 per child per annum in day schools and £72 in residential schools To lower the school age for these children would require legislation

Replying to Mr Edwards on April 21st Sir D Maclean said that at the same date the number of educable mentally defective children ascertained by local medical officers in England and Wales was about 12 100—18 700 boys and 11 400 girls It was known that the actual number of such children was considerably larger There was accommodation in special schools for about 16 600 mentally defective children and the average cost of the education was about £24 per child per annum in day schools and £67 in residential schools Sir D Maclean said he would inquire into the statement that mentally defective children were very often mixed up with deaf children at schools for the deaf and that if such was not the case much more accommodation would be available for those who were merely deaf He was not prepared at present to call on local authorities to provide school accommodation for the mentally defective children above the number for whom it was now available

Flood Relief for China

On April 25th Sir John Simon replying to Mr Idris Davies said that in September 1931 the Assembly of the League of Nations adopted two resolutions in regard to the floods in China and the Council of the League instructed the Secretariat to communicate copies to all the Governments In response to this appeal many contributions were made directly to China and in addition the following were notified to the League Contributions in money were made by the Belgian and United States Red Cross the Red Crescent Society of Turkey and the Swedish Red Cross Contributions of medicines etc were made by the University of Toronto the State Serum Institute of Denmark the Pasteur Institute of Saigon and the Governments of Egypt Indo China India the Netherlands the Netherlands East Indies Norway Poland Spain Sweden and Yugoslavia Contributions of medical personnel were made by the Governments of Egypt the United States Indo China the Netherlands East Indies and Spain When the laboratory resources of China were organized in view of the necessity for vaccines and serums all needed supplies were produced without difficulty so that the health authorities found it unnecessary to accept many offers of this kind Among contributions actually sent was one of anti-plague vaccine from the Government of India The medical director of the Health Section of the League arrived at Nanking in September and placed himself at the disposal of the Chinese Government and the Flood Relief Commission He remained in China till late in December Professor Cimen and Drs Borcic C I Parl A Stampar and I I Hurng all of the League Health Organization made surveys gave advice and organized anti-epidemic campaigns These activities were co-ordinated by Sir J Hope Simpson who at the request of His Majesty's Government placed his services at the disposal of the Chinese Government and was appointed to be head of the National Flood Relief Commission

Indian Medical Council—Sir S Hoare replying to Mr Morgan Jones on April 25th said that the Indian Medical Council Bill was introduced in the Indian Legislative Assembly on March 23rd He had not yet heard whether it had made further progress

Blind Statistics—Replying on April 21st to Mr Hutchison Major Elliot said the latest returns from local authorities showed that the number of registered blind persons in England and Wales was 52 727 on March 31st 1929 According to unofficial figures obtained from the Counties Associations for the Blind there were 60 598 registered blind persons in England and Wales on March 31st 1931 and the number of registered blind persons in Scotland was 8 821 The number of blind persons in receipt of pensions under the Blind Persons Act 1920 on December 31st 1931 the latest date for which figures were available was 24 387 In reply to Mr Magnay Mr Ernest Brown said the increase in the number of the registered blind was probably due to more complete registration and did not necessarily indicate any actual increase in the number of blind persons Many persons who had been blind for some time but were previously unaware of the services provided under the Blind Persons Act had been led to seek registration in order to obtain the benefits available under that Act

Slum Clearance by Wallasey Corporation—Replying to Dr Clayton on April 21st Mr Ernest Brown said that the clearance orders made by the Wallasey Corporation concerning houses in the Moreton area of Wirral had been the subject of the prescribed local inquiry and that with certain modifications the areas concerned had properly been declared to be clearance areas In the circumstances the Minister of Health had no power to mitigate any hardships incurred by occupants Mr Rhys Davies asserted that this area was one of the most insanitary in the country

Opium Manufacture—On April 25th Sir S Hoare said that information as to the quantity and value of the opium manufactured in 1931–32 at the Government of India's opium factories was not yet available

Foot and Mouth Disease in Kent—Sir J Gilmour states that no fresh cases of foot and mouth disease have been confirmed in Kent or elsewhere in Great Britain since that of April 18th at Chertton The herd of 70 cattle in which affected animals were discovered was slaughtered and the remaining stock on the farm treated with serum as a protective measure The origin of this outbreak had not yet been discovered

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The Linacre Lecture (1932) will be given by Dr J J R Macleod F R S Regius Professor of Physiology University of Aberdeen on Friday May 6th in the Anatomy lecture theatre at the new museums

UNIVERSITY OF LONDON

The following candidates have been approved at the examination indicated

DIPLOMA IN PSYCHOLOGICAL MEDICINE (*with Special Knowledge of Psychiatry*)—J J Cleg. D C Dewar

UNIVERSITY COLLEGE

The examination for the Bucknill Scholarship value 160 guineas and for two exhibitions value 55 guineas each will begin on May 23rd The subjects for the examination are chemistry physics botany and zoology The scholarship and the two exhibitions are tenable at University College London *Entry forms* should be obtained from the secretary of University College not later than May 9th

UNIVERSITY OF GLASGOW

To the list of recipients of the M D degree (with commendation) published last week at page 777 should be added the name of George Brown

The Services

ARMY ADVISORY COMMITTEE ON MAXILLO FACIAL INJURIES

The War Office announces that a Standing Advisory Committee under the Director General Army Medical Services has been formed in order to investigate and report on the treatment of maxillo facial injuries The committee will make recommendations in regard to the provision of special facilities and equipment for these cases the general methods of treatment and the training of dental officers in the principles of preliminary treatment in the field

The following are the members of the committee at present appointed Colonel J P Hellwell C B E As is tant Director General A M S for Dental Services (Chairman) Mr W Kelsey Fry *M C* M R C S L D S (appointed by the British Dental Association) Sir Harold D Gillies C B E F R C S Mr W Warwick James O B E F R C S L D S Major S H Woods O B E The Army Dental Corps (Secretary)

Medical News

The discourse to be given by Sir William Bragg at the Royal Institution conversazione on Friday evening May 6th will be related to the various developments in pure and applied science which have depended on the use of the x ra methods of analysing crystal structure In order to supplement the discourse an exhibition is being arranged which will demonstrate more fully the work that has been done Members of scientific societies or senior students of universities and technical institutions and others interested in this work will be welcome if they present themselves at the Royal Institution 21 Albemarle Street W 1 at any time between 10 a m and 6 p m on May 9 h or 10th The managers request such visitors to leave their names and addresses

A course of lectures on the contributions of psycho analysis to anthropology will be given by Dr Susan Isaacs on Friday evenings at 8 30 from May 6th to June 24th at the London Clinic of Psycho Analysis 36 Gloucester Place W 1 The lectures are intended for medical practi tioners medical students and students of anthropology fee for the course £2 2s to be paid to Dr Bryan 35 Queen Anne Street W 1

The annual meeting of the Lebanon Hospital for Mental Diseases near Beirut Syria will be held at Friends House Euston Road N W 1 on Wednesday next May 4th at 3 o clock with Dr E W G Masterman in the chair The speakers will include Dr Nathan Raw and Dr Doris Odlum

The West Kent Medico Chirurgical Society will hold a dinner and dance at Chesman s Restaurant Lewisham S E on Thursday May 12th at 7 30 p m Guests may be invited The price of the ticket is 7s 6d (exclusive of wines) Applications for tickets should reach the honorary secretary (Dr C J B Buchan 267 Baring Road Grove Park S E) by April 30th

The eighty seventh half yearly dinner of the Aberdeen University Club London will be held at the Trocadero Restaurant at 7 for 7 30 p m on Thursday May 19th under the chairmanship of Sir Arthur Keith M D F R S Rector of the University Secretary s address 9 Addison Gardens W 14

The National Safety Week Council announces that instead of one national safety week throughout Great Britain it is arranging this year a series of weeks in various localities at different dates The principal week will be held in London from May 2nd to 8th and the National Safety Congress will be held concurrently from May 4th to 7th A list of the safety weeks so far arranged and detailed information may be obtained from the National Safety First Association 119 Victoria Street S W 1

In aid of King Edward s Hospital Fund a further series of Mock Trials will be held in the theatre of the London School of Economics on Tuesdays May 3rd 10th 24th 31st and June 7th and 14th at 5 30 p m The programme of indictments and full particulars may be obtained from the secretary King Edward s Hospital Fund for London 7 Walbrook E C 4

The Fellowship of Medicine and Post Graduate Medical Association announces an afternoon course in diseases of the skin at St John s Hospital Leicester Square May 2nd to 28th a course in physical medicine at the London Light and Electrical Clinic Ranelagh Road on Mondays and Wednesdays from May 2nd to 25th at 9 p m and a week end course in clinical surgery at the Royal Albert Dock Hospital May 7th and 8th A lecture demonstra tion on rheumatic infection and heart disease in children will be given at 10 30 a m by Dr B Schlesinger at the Children s Heart Hospital West Wickham on Saturday May 7th (applications to the Fellowship not later than May 3rd) Epidiascope and laboratory demonstrations will be given by Dr Knyvett Gordon at 10 Bedford Square on Wednesdays May 18th 25th and June 1st at 5 30 p m Particulars of all courses may be had from the Fellowship of Medicine 1 Wimpole Street W 1

A post graduate course on diseases of the nervous system will be held at the National Hospital for Diseases of the Nervous System Queen Square W C from May 9th to July 1st It will consist of thirty two clinical lectures and demonstrations teaching in the out patient department and pathological lectures and demonstrations The fee for the course will be £6 6s A course of ten lectures on the anatomy and physiology of the nervous system will be arranged on Tuesdays and Thursdays at 12 noon if there are sufficient applicants fee £2 2s A course of ten clinical demonstrations chiefly on methods of examination of the nervous system will be given on Tuesdays and Thursdays at 5 p m fee £2 2s

The Metropolitan Branch of the Society of Medical Officers of Health has accepted an invitation for its members to visit the Cow and Gate Milk Powdering Factories at Wincanton and Somerton Somerset on Friday May 6th

A conference of the Southern Region (Western Section) of the British Health Resorts Association is being held this week end at Bournemouth At the morning session on Saturday with Sir Thomas Oliver in the chair Dr R Fortescue Fox will discuss Centres of convalescence the role of medical baths and papers will be read by Drs J Browning Alexander H Gordon Smith and Harold Simmons At the afternoon session with Dr Alfred Cox in the chair Colonel R H Elliot will discuss The human side of the movement and Dr W S C Copeman the medical policy of the British Health Resorts Association

According to the *Times* authorities at Havre are investigating some three hundred cases of poisoning amongst the crews of merchant vessels which have touched the port during the last three months The cause of the outbreak is attributed to arsenic in quantities from 0 46 to 0 77 of a grain per litre in a stock of Spanish wine forwarded to various shipping companies for the use of their crews At present opinion is divided as to whether some arsenious compound has been used for spraying the vines or some alkali intended to reduce the acidity of the wine has been contaminated with arsenic

Messrs H K Lewis and Co Ltd announce for early publication volume 1 of *A Short Practice of Surgery* by Mr Hamilton Bailey and Mr McNeill Love volume II will be issued a little later

Messrs George Allen and Unwin Ltd official agents for the publications of the League of Nations announce that the League has decided to publish the material issued by its Health Organization in a new periodical entitled the *Quarterly Bulletin of the Health Organization* the first number of which will be issued shortly

Dr W H France of Selston was called to the Bar by Gray s Inn on April 20 n

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR British Medical Journal British Medical Association House, Tavistock Square, W.C.1.** ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISMENTS as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861 9862 9863 and (after normal exchange hours) 9864.

The TELEGRAPHIC ADDRESSES are

EDITOR OF THE *BRITISH MEDICAL JOURNAL* *Articulate, Westcent, London*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements etc.) *Articulate, Westcent, London*

MEDICAL SECRETARY *Medisecra, Westcent, London*

The addresses of the Irish Office of the Parliamentary Medical Association are 16 Fitzwilliam Street Lower, Dublin (telegrams *Bacillus, Dublin*, telephone Grosvenor Dublin), and of the Scottish Office 7 Drumsheugh Gardens, Edinburgh (telegrams *Associate, Edinburgh*, telephone 24761 Edinburgh).

QUERIES AND ANSWERS

Plantar Corns

Dr. ERNEST J. HARRIS (Southport) writes: The best treatment for plantar corns and callosities is a piece of pumice-stone, chosen by trial, which floats well in water. This should be rubbed dry and wet with plain or soapy water several times a week. If the plantar arches are drawn up part of the load is taken off the corn and more readily by the wizard support in which the foot can be placed. The corn should be given to the foot rather than the foot to the corn, so that the boots which should be fitted so as not to cramp the foot especially in width and the upper surface of the shoe must be examined as to freedom from creases in the leather or inequalities of the surface which are liable to be produced during wear. A change of boots daily is desirable and usually frequent washing of the feet.

Income Tax

Disability Pension

I. E. M. O. has retired and has been awarded a permanent disability pension. Will he be liable to pay tax on it?

Yes, it is presumably paid to him in connexion with the pension scheme to the funds of which he has made compulsory contributions and represents income to which he has acquired a legal right.

LETTERS, NOTES, ETC.

Anaesthetic Masks

Dr. I. O. SULLIVAN (Monmouthshire) writes: I note Mr. H. M. Page's letter in your issue of April 23rd stating that before the war he devised a mask identical to the one published in the *British Medical Journal* on April 16th. As mentioned I was not aware that an identical mask was already in existence. In consequence I do not claim priority as being the originator of this mask. I have since received an illustration of Mr. Page's mask from Messrs. Allen and Hanburys and although the masks appear identical there are a few differences—namely, the mask devised by Mr. Page is shallower than mine, the perforations inside the tubes also differ in so far as mine extend almost the whole length of each tube while in his model they are confined to the dome.

Dr. A. M. DUFF (honorary anæsthetist Clayton Hospital, Wakefield) writes: In the *Journal* of April 16th under Preparations and Appliances Dr. I. O'Sullivan describes the anæsthetic mask which he has devised. I had a mask made for me two or three years ago somewhat similar in type. I brought the tubes from side to side with perforations on either side of the middle line. It was made in this way in order that the rubber tubes from the cylinders might be brought in from the more convenient side. The mask was made by Mr. C. F. Thackray, Leeds.

Dr. O. R. I. WILSON (Streatham) writes: I would like to point out that my father the late Dr. R. W. Wilson, medical superintendent of the Croydon Infirmary, used a similar appliance over twenty years ago for use with a Junker's inhaler. In this mask however there was only one perforated metal tube into the summit of which was inserted a Y piece to the ends of which were attached rubber tubes from the inhaler and from an oxygen cylinder.

Doctors and District Nurses

NURSE writes: I fear that my original letter has been misconstrued. With over twenty-five years in my present district in extensive industrial practice including Poor Law and having passed through chairs both of my Division and French Committee in this matter. The relationship between doctor and nurse was not directly at least foremost in my mind. As to the futilities of local nursing committees I sympathize with A. Devon G.P. I have had some but brought away three of their nurses to join me in the public sphere. Might I point out that the question is one come rank the patient I cannot do better than quote from one of the highest rank in our Association to whom I submitted the issue before writing to the *Journal*. I entirely agree that medical men are not doing their duty by their patients who neglect to use a trained nurse in suitable cases when they have the chance.

Dr. H. I. BRONSOM (Hurford, Gloucestershire) writes: As most of the letters have condemned district nurses I think it fair that Dr. Bartlett's views should be supported. In my practice there are five district nurses and I have ample opportunity of judging their work. Without their help in dealing with innumerable minor ailments and above all of relieving me of routine midwifery, which used to make the lives of my grandfather and father far less pleasant than mine it would really be impossible to carry on a wide country practice. They probably make many mistakes but I have never known them to make a serious one and I have always found them a skilful and devoted class of women.

Medical Golf

Dr. WILMER C. LOWRY (Blyth) writes: On Sunday April 17th the annual golf match of the Blyth Division of the British Medical Association took place. Ten members turned out. The weather was ideal and the afternoon most successful. Dr. Milne returned a score of 77 net (handicap 1), Dr. Gordon 78 net (handicap 16), Dr. J. Brown and Dr. Lowry 86 net (handicap 14). Dr. J. Brown and Dr. Macauley take this event as the occasion of their only game of the year, perhaps enjoyed the match more than anyone else. Dr. Brown scored 137, Dr. Lowry 198. Dr. Lowry however was one hole up at the end. Both clubs the victory. The thanks of the Division are due to the golf secretary Dr. C. Hartle for a very pleasant day.

Brain of the East African Native

Dr. NORMAN LEYS (formerly medical officer in Kenya and Nyasaland) writes: In your issue of March 26th Dr. J. H. Sequeira cites figures that make it appear that the average weight of the brain of the natives of East Africa is less than it is in Europeans. As the weight of the brain in all races is known to vary with the weight of the whole body and as in the figures Dr. Sequeira cites no correlation of brain with body weights has been made they would seem to be of no value.

B. Aerogenes as an Index of Water Purity

Correction

Dr. J. D. ALLAN CRAY (Bacteriological Laboratories, University of Liverpool) writes: The abstract in the *Epitome* of April 16th (p. 72, No. 369) of a paper written by me states: "He finds that the use of modifications of the citrate medium containing lithium or barium is useful in the isolation of *B. aerogenes* when *B. pyocyaneus* is abundant." Little if any danger appears to accrue from ingesting the latter organism even in large numbers. As the original paper indicates the sentence should run: "Little if any danger appears to accrue from ingesting *Bact. aerogenes* even in large numbers."

Vacancies

Notifications of offices vacant in universities medical colleges and of vacant resident and other appointments at hospitals will be found at pages 38, 39, 40, 41, 44, 45 and 46 of our advertisement columns and advertisements as to partnerships assistantships and locumtenencies at pages 42 and 43.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 207.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

388 Transient Ventricular Fibrillation

Transient syncopal attacks in patients with permanent auriculo-ventricular dissociation are mainly due either to complete standstill of the ventricles or to various grades of acceleration leading to ventricular fibrillation S P SCHWARTZ (*Arch Int Med* February 1932 p 282) records a case of auriculo-ventricular dissociation in which sixty-seven seizures of unconsciousness occurred during a period of seven months Each seizure was associated with periods of ventricular fibrillation the longest recorded attack with spontaneous recovery lasted six minutes and two seconds The electrocardiographic alterations preceding a seizure consisted of a gradual acceleration of both the basic auricular and ventricular rates Periods of re-excitation of from four to eleven beats were noted during the premonitory period heralding the approach of unconsciousness The onset of every recorded seizure of ventricular fibrillation in this patient was initiated by a ventricular extrasystole of constant character and location in the ventricle Spontaneous revival usually coincided with cessation of ventricular fibrillation the mode of recovery was variable but the restoration of the basic rhythm was preceded by an idio-ventricular rhythm with a slightly irregular ventricular rate following usually a post-undulatory pause Schwartz believes that this condition is much commoner than has been thought and that transient ventricular fibrillation may be suspected in such patients if preceding a period of unconsciousness the heart rate increases above that of the usual basic rate

389 Cutaneous Manifestations of Meningococcal Infection

A ATTAL (*Thèse de Paris* 1931 No 532) who records three illustrative cases in patients aged 2½ 4 and 45 years respectively states that meningococcal infection whether generalized as septicaemia or localized in the form of meningitis may be accompanied by cutaneous manifestations Some of these are frequent such as herpes purpura and papulo-nodose eruptions The others are rare —namely the maculo-vesicular *morbilliform* and scarlatiniform rashes rose spots and the varicelliform and herpetiform eruptions Although none of these eruptions is peculiar to meningococcal infection the presence of herpes purpura or a papulo-nodular eruption accompanied by attacks of intermittent fever simulating malaria or by a *slight meningeal reaction* as shown by nuchal rigidity and Kernig's sign should suggest the possibility of meningococcal infection and prompt its investigation by blood culture in the stage of septicaemia or lumbar puncture in the meningeal stage

390 The Age Incidence of Tuberculosis in Women

O HELMS (*Hosp Tid* January 6th 1932 p 45) has investigated the age incidence of pulmonary tuberculosis in 1 000 women treated at his sanatorium in Denmark The first symptoms appeared in most of these cases between half a year and one year before admission to the sanatorium and his records refer to the age at which these symptoms first appeared There were only 20 patients under the age of 15 at the first onset of symptoms At the age of 15 there were 41 and after this age there was a rapid rise which achieved its maximum at 21 the number of cases at this age being 74 Between 21 and 24 there was a slow decline from 24 onwards it became abrupt There were only 185 women whose first symptoms began after the age of 29 whereas between the ages of 15 and 29 there were as many as 795 So far as tuberculosis is concerned the dangerous age for women would seem to be within the narrow limits of 15 and 24 during which approximately three-fifths of all cases develop This dangerous age particularly between 15 and 20 corresponds broadly to the age at which most young women leave their homes to work in other homes or in offices where they are overworked and underfed in many cases Of the unmarried patients more than four-fifths had to earn their own living among the 338 married patients there were only 12 whose consorts had suffered from tuberculosis but in as many as 232 cases there was a history of deaths from tuberculosis within the family With regard to the possibilities of preventing the outbreak of tuberculosis within these narrow age limits in women the author is doubtful whether more can be done than is already done in Denmark with its ample supply of doctors insurance societies tuberculosis dispensaries sanatoriums and hospitals Early diagnosis is important but he doubts if it would be feasible to supervise at suitable intervals with stethoscope and x-rays all the women concerned Yet it would seem reasonable to examine every half-year the younger members of the female staff of hospitals The author discusses the alternatives of endogenous or exogenous infection in his cases without committing himself exclusively to either process

391 Jaundice in Lobar Pneumonia

L PRETI (*Il Policlinico* Sez Prat February 22nd 1932 p 283) who records an illustrative case states that jaundice occurring in the course of pneumonia may be due to an intense haemolytic process which takes place in the pulmonary exudate during the process of red hepatization Both clinical and experimental data indicate that the transformation of blood pigment into bile pigment may be brought about in the affected lung The jaundice so produced does not affect the prognosis but should merely be regarded as a symptom due to an intense destruction of the red cells For this no special treatment is required since it gradually disappears as the pneumonia progresses Preti's patient was a woman aged 40 who developed jaundice on the fifth day of an attack of double lobar pneumonia The issue of the case is not recorded

Surgery

392 Prostatic Calculi

A LAZARUS and A ROSENTHAL (*Urol and Cut Rev* February 1932 p 99) who record fifteen personal cases state that 370 cases of prostatic calculi have been reported though many more are encountered than are published Until the introduction of radiography into the routine urological examination prostatic calculi were supposed to be rare but modern methods of investigation have shown that they are not uncommon As regards their aetiology the present writers hold that calculi of the prostate like those found elsewhere in the body are due to a variety of causes In the majority of cases a pre-existing infection within the gland in an individual with a tendency to calcium deposit seems to be the most likely explanation for calculus formation The calculi vary in size consistency and chemical composition The nucleus is usually composed of epithelial debris blood clot bacteria corpora amylacea and necrotic tissue the surrounding layers are made up of calcium carbonate calcium phosphate calcium oxalate and ammonio-magnesium phosphate Most prostatic calculi are found in the lateral lobes and occasionally in the median ones while the anterior and posterior lobes are rarely if ever involved The calculi are usually multiple but thirty-three cases are on record in which only a single stone was seen Most of the cases are found after puberty the majority occurring in the fifth decade and two-thirds of all the cases in the fourth fifth and sixth decades In the present writers' series the youngest patient was 25 and the oldest 75 Prostatic calculi often give rise

to no symptoms and are accidentally discovered in a routine urological examination by x rays and digito rectal exploration In a fair number of cases the following symptoms occur in order of frequency diurnal and nocturnal pollakiuria dysuria and ardor urinæ perineal penile and rectal pain urgency and tenesmus hæmaturia retention impotence and hæmato permia The diagnosis is established by rectal examination and radiography Prostatic calculi must be distinguished from chronic prostatitis with hard nodules inflammatory and malignant infiltration and tuberculosis of the prostate Complete cure follow the removal of the calculi but if the condition is left untreated abscess formation cystic degeneration gangrene or carcinoma may result Suprapubic prostatectomy in two stages is the operation of choice if no symptoms are present diathermy followed by massage is sufficient

393 Pneumococcal Peritonitis

NOVI JOSSELAND (*Journ de Med de Lyon* February 20th 1932 p 99) holds that pneumococcal peritonitis is most often due to a blood infection but that the causative organism can also reach the peritoneum through the diaphragm the intestinal wall and the uterus In the first few hours there is only some swelling of the mesenteric glands with vascular congestion of the small intestines which have a characteristic shiny feel on palpation At the end of twenty four hours there is a little mucous exudate but it is only on the second day that the effusion even if purulent is appreciable The condition usually occurs in young girls suffering from some pleural or pulmonary infection rhino pharyngitis otitis or vulvo vaginitis The onset is sudden with colic diarrhœa vomiting and a temperature rising rapidly to 104° F A few hours later the pain and vomiting diminish and the temperature drops to a level of 100 5° to 101 5° F a similar apparent remission may occur in pneumonitis but not so characteristically Examination of the abdomen will reveal very slight distension no muscular defence and no tenderness in the right iliac fossa The syndrome is not always so typical The onset may be a general peritonitis with abdominal distension or it may be insidious with a temperature of 101 5° to 102° and pain in the right iliac fossa Diarrhœa is absent there may even be constipation Cure by resolution occurs fairly often but severe relapses may occur or grave and fatal complications The author advises against immediate operation if the diagnosis is definite When it is in doubt the case should be watched from hour to hour so as to permit surgical intervention at the earliest indication The operation in such cases should be under local anæsthesia and be confined to exploring the appendix and draining the pouch of Douglas At the end of 24 to 48 hours a decision is easier since the clinical signs are clearer There may be (1) a general peritonitis when an operation can do no harm and may cure (2) a resolving condition or (3) localizing peritonitis in which event operation should be postponed to the third week

394 Erysipelas Gangrenosa

S NUSSBAUM (*Arch of Ped* January 1932 p 17) who records an illustrative case states that this condition differs from the usual form of erysipelas in the diffuse margin of the rash type a streptococcus being the causative agent instead of type β the large deep ulcerations of the skin formed in the path of the rash and the low blood count He has found only two other cases on record (reported by Hoesch and Schilling respectively) both of which occurred in adults Nussbaum's patient was a girl aged 11 years in whom the portal of entry of infection was formed by the cracks of ringworm infection between the toes The onset was sudden with a high temperature and a diffuse rash which extended from the toes of the right foot to the groin Extensive ulcers developed in the right foot and two on the leg Recovery took place after nineteen days *Streptococcus viridans* was grown from the abscess Blood cultures were negative the red cell count ranged between two and three millions and the leucocyte count between 5 200 and 7 200

Therapeutics

395 Oxygen Therapy

M B ROSENBLÜTH (*Journ Amer Med Assoc* January 30th 1932 p 396) remarks that in the tents in general use for the administration of oxygen provision is usually made for the removal of excess of carbon dioxide by circulating the atmosphere of the tent through a container filled with soda lime This soda lime has to be renewed every 48 hours it introduces additional expense into the treatment and the author does not think it is necessary when large quantities of oxygen are being used With ordinary nursing care he states the oxygen content of a tent cannot be maintained at a desirable level if the flow of oxygen is less than 8 litres in each minute If special care is taken to prevent leakage the oxygen content can be raised to over 45 per cent of the tent atmosphere with a flow of 6 litres a minute but the carbon dioxide proportion will then approach 4 per cent When however the flow of oxygen is maintained at 8 to 10 litres a minute the carbon dioxide content will not rise above 1 5 per cent Rosenbluth found that patients kept in atmospheres containing between 2 and 4 per cent carbon dioxide did not experience any unpleasantness or show untoward symptoms He adds that the expense of the additional supply of oxygen necessitated is very small when compared with the saving in the cost of the soda lime there is also the additional advantage that less exacting care is imposed on the nursing A further benefit so derived is that the interruption of the treatment which is inevitable while the soda lime is being changed is obviated

396 Treatment of Severe Purpura

I GOLDSCHMID (*Derm Woch* February 6th 1932 p 198) records a case of severe anaphylactoid purpura in a male infant aged 18 months accompanied by fever pains in the joints constitutional disturbance and an urticarial eruption Rapid improvement and finally complete recovery followed intramuscular and intravenous injections of a 10 per cent solution of calcium gluconate accompanied by intramuscular injections of blood Gold schmid states that during the last three years hundreds of cases in the dermatological municipal hospital at Hanover have been treated by injections of calcium gluconate without any symptoms of irritation or infiltration developing

397 Results of the Modern Treatment of Syphilis

L LOMHOLT (*Ugeskrift for Læger* February 4th 1931, p 123) has made a statistical study of about 3 000 cases of syphilis treated at two of the principal hospitals in Copenhagen in the period 1920–27 Among these cases were 1 797 which fulfilled the following conditions they were recent they had not been treated previously and they submitted to treatment for more than half a year They were classed in three groups according as the disease was (1) primary with a negative Wassermann reaction (2) primary with a positive Wassermann reaction and (3) secondary The treatment was more or less uniform throughout the period under review but it was not quite identical in the two hospitals Irregularity of attendance of some patients further interfered with the uniformity of the treatment which in principle consisted of large weekly injections of salvarsan or neosalvarsan (about 60 cg of neosalvarsan for women and 75 cg for men the corresponding doses of salvarsan being respectively 40 and 50 cg) Six or seven injections were given in each course the first of which was supplemented by mercury or bismuth The dosage duration and spacing of the subsequent courses lacked uniformity As regards the results of this treatment subsequent clinical manifestations occurred in 4 6 per cent and serological relapses (a positive Wassermann reaction) in about 10 per cent These serological relapses were about twice as common in women as in men In 1921 a fellow countryman of the author B Pontoppidan published a study of 1 396 cases of syphilis treated in the same two hospitals in the

period 1910–14 with greatly varying doses of salvarsan combined with mercury Pontoppidan found the same percentage (about 10 per cent) of serological relapses as did the author but while he observed clinical manifestations of the disease after treatment only in 4 6 per cent Pontoppidan observed them in 22 per cent Accordingly it would seem that the specific treatment of syphilis in Copenhagen has become more effective since 1920 than it was before that year and that the reduction in the incidence of clinical manifestations of the disease must entail a reduction in the number of new infections

Disease in Childhood

398 Multiple Fractures in a Newborn Infant

A case of multiple fractures in a newborn infant is reported by C JEANNIN M SUREAU and R WEILL SITRE (*Bull Soc d Obstet et de Gynecol de Paris* January 1932 p 31) It was diagnosed as corresponding to a transition form existing between the two extreme types of congenital fragility of the bones (periosteal dysplasia) and osteo psathyrosis At birth the infant showed shortening of all the limbs which were incurved and knotty Over the shafts of the long bones were abnormal swellings at the level of which crepitation was obtained The right and left clavicle were also fractured Altogether there were about thirty fractures The cranium was almost entirely membranous only the inferior parts of the occipital frontal and parietal bones being ossified The sclerotics were definitely blue No abnormality was found in the viscera Clinical examination of the parents revealed nothing pathological there was no evidence of endocrine disorder The Wassermann reaction was negative in both So far as could be ascertained no relatives had suffered from bony defects Radiological examination confirmed the existence of the fractures and showed that the centres of ossification were normal Contrary to expectation the infant lived and two months after birth he was clearly improving Mercurial inunction was given from birth followed by ultra violet ray treatment and irradiated vitamins together with calcium phosphate and arsenic No further fractures occurred after birth The blue of the sclerotics persisted The authors consider that the condition is probably best described by the term osteogenesis imperfecta They add that during the fifth month of pregnancy the mother had exhibited a slight albuminuria associated with a marked loss of phosphates

399 Treatment of Kala azar in Children

The prognosis of kala azar in children has radically improved since the introduction of antimony salts in its treatment P GIRAUD and MLLE COULANGE (*Presse Med* February 3rd 1932 p 178) describe the use of three preparations which may be advantageously employed a mineral compound (stibyal or the emetic sodium antimony tartrate) and two organic compounds (*stibenyl* and neostibosan) Stibyal which is preferable should be administered only intravenously in a *1 to 2 per cent* solution and be injected very slowly The commencing dose of 2 to 3 cg should be progressively increased according to age to 5 to 10 cg for children aged 10 years and over The requisite number of doses varies with the individual To be efficacious this treatment must be given uninterruptedly *until cure is effected* Stibenyl can be administered both intravenously and intramuscularly this drug however is difficult to obtain since it is no longer manufactured Neostibosan can also be administered in both these ways A series of eight injections (three per week) should be given the initial dose is 5 cg and 10 cg for the remaining ones for children up to the age of 4 years The effects of treatment and such conditions as intolerance intoxication and resistance to treatment are discussed Adjuvant measures (attention to the general hygiene blood transfusion liver therapy and actinotherapy) are also recommended The evolution of the disease under this treatment and its encouraging results are fully described and short notes on three cases are appended

400 Epidemiological Factors in the Pneumonia of Children

SELMA M SHULTZ (*Amer Journ of Hyg* January 1932 p 80) records a study of pneumonia in children which shows that as in adults the principal modes of transmission of the disease are the normal carrier and the convalescent patient and that preventive measures can only be directed to the control of these The examination of eighty six persons who were associated with twenty one children with pneumococcal pneumonia revealed in eleven carriers the presence of the same type of pneumococcus as that isolated from the patient There was no significant variation in the virulence of the pneumococcus isolated from the cases and the corresponding carriers The virulence of Type I organisms from cases and carriers was higher than that of Types III or V recovered from the cases The duration of the carrier state followed in thirty five convalescent children ranged from 2 to 152 days Types I and III remained longer in the pharynx than Type II or the subdivisions of Group IV The pneumococci which were found to replace the infecting type did not differ greatly from those detected in the pharynx of the healthy contact The unclassified pneumococcus which apparently replaced the infecting type might in some instances have been a degraded form of the original strain Two children who developed symptoms of pneumonia in hospital were studied as regards the possibility of ward infection but the sources of their infection could not be traced

Obstetrics and Gynaecology

401 The Prognosis in Forceps Cases

S STEFANIK (*Bratislavske Lekarske Listy* February 1932 p 67) states that in the obstetric gynaecological clinic of Bratislava during the years 1912 to 1931 557 patients (5 6 per cent) were delivered by the application of low forceps and 125 (1 2 per cent) by means of high forceps The indications for the application of forceps were danger to the mother in 296 cases (43 4 per cent) danger to the child in 272 cases (39 9 per cent) and danger to both in 114 cases (16 7 per cent) Primiparae formed 75 per cent of all cases in which forceps were applied The mortality among the children delivered by means of forceps was 6 3 per cent in low forceps cases and 24 8 per cent when the high forceps procedure was employed Injury to the child resulted in 33 per cent in low forceps and 84 2 per cent in high forceps cases asphyxia occurred in 32 8 per cent and 56 per cent respectively The maternal mortality was 0 9 per cent for low forceps operations and 2 4 per cent in high forceps injury to the mother resulted in 72 6 per cent and general maternal illness followed in 18 2 per cent and 31 8 per cent respectively The author concludes that the application of forceps is a serious and dangerous procedure its employment should therefore be limited as much as possible

402 Hysterectomy after X Ray Sterilization

P CAFFIER (*Zentralbl f Gynak* January 9th 1932 p 89) agrees with v Peham that in recent years an increasing number of patients appear to need hysterectomy in spite of previous sterilization by x radiation of the ovaries He analyses the cases of 30 such patients treated at the Berlin Universitats Frauenklinik from 1928 to 1931 There were two cases of ovarian cystoma developing after x radiation for myoma uteri bleeding had ceased for nine or ten years There were four carcinoma cases three being corporeal and one cervical In these six cases the malady needing treatment was different from that for which radiotherapy had been used but its onset would have been prevented had hysterectomy been performed The remaining cases coming to

operation were 18 of myoma and 6 of metropathy in these with one exception irradiation could be regarded as having been unsuccessful The myoma cases in 14 of which renewed hæmorrhage was reported comprised 2 of submucous myoma with tout pedicle 5 of sessile broad based submucous myoma 7 of intramural and 1 of chiefly subserous myoma The 6 metropathic cases all characterized by persisting or renewed bleeding included 3 of adenomyoma (In the one period after 151 operations for myoma or metropathy the after operation mortality amounted only to 5 per cent At other clinics from three to eight per cent of surgical interventions after unsuccessful x ray castrations have been reported) Analysing the 17 cases of failed radiotherapeutic treatment of myoma Cahier concluded that in 3 the situation or size of the tumour should have contraindicated x ray treatment The fact that the remaining 14 seemed clinically suitable for such treatment and that in 5 no pathological explanation (softening or necrosis) of renewed or persisting symptoms could be found are taken as affording further support of systematic operative rather than systematic x ray treatment of uterine myomata

103 Glycosuria in Pregnancy

Ellis V Chase (*Canadian Med Assoc Journ* March 1932 p 279) points out that the appearance of sugar in the urine of a pregnant woman is often physiological it has been variously attributed to increased permeability of the renal epithelium to overactivity of the breasts or thyroid gland and to functional changes in the ovaries and placenta It requires no treatment and does not apparently predispose to diabetes from which condition it is differentiated by the small amount of sugar present the absence of thirst and the normality of the blood sugar curve V J Harding and D I Sharp (ibid p 283) have however found that such physiological glycosuria may be associated with thirst polyuria and pruritus vulvæ presumably due to a low renal threshold and not associated with definite diabetic symptoms In the urine of a fasting pregnant woman only very concentrated sugar is absent True acetone is never found in this form of glycosuria the Le Nobel variation of the nitroprusside test is however more reliable in these cases than the usual Rothera procedure since the latter reacts also to certain substances present in the urine of pregnancy which are not acetone though resembling it The authors see no clinical value in distinguishing such glycosuria from lactosuria in view of the uncertainty of such distinction when the tests at present in general use are employed

Pathology

401 Basal Metabolism at Puberty

A St Lotter and Hannah Meyer (*Amer Journ Dis Child* February 1932 p 327) have studied the basal metabolism in girls and boys between the ages of 10 and 16 at intervals of six months to a year over a period of from one to four years The Krogh respirometer and later the Benedict Roth apparatus were used and each child had a preliminary trial before the first recorded test so as to eliminate such factors as excitement or anxiety The authors found an increase in the basal metabolic rate in the prepubescent period which reached its maximum about the time when menstruation was established in girls and boys became sexually mature there was subsequently a decline No uniformity appeared to maintain as regards the height of the increased metabolism or its duration Some of these children had no other symptoms of an overacting thyroid gland but in certain cases there was thyroid enlargement with tremor nervousness vasomotor instability cardiac murmur and tachycardia All these symptoms disappeared as the basal metabolic rate returned to its previous normal level when puberty was well established The authors conclude that there is a physiological increase in the basal metabolism during the approach to puberty this coincides with the physiological rather than the chronological age and occurs earlier in girls than in boys coincident with their earlier pubescence Since there appears to be an individual variation in the height and duration of the increased metabolism it is difficult to define normal standards for this important age period The increase may be associated with symptoms simulating organic heart disease or more especially exophthalmic goitre and, consequently such clinical manifestations of pubescence must be borne in mind when high metabolic figures are recorded Exophthalmic goitre is rare before puberty and should not be confused with the physiological overactivity of the thyroid gland in pubescence which is only temporary and has an excellent prognosis

405 Action of the Splanchnic Nerves on the Spleen

J Barcroft Y Nishimaru and S R Puri (*Journ of Physiol* March 7th 1932 p 321) show from experiments on cats that the nerve fibres to the spleen and suprarenal bodies are carried chiefly through the greater splanchnic nerve Stimulation of this nerve produces a contraction of the spleen which is followed by rhythmical contraction This is due partly to a direct action on the spleen and partly to an indirect one through the stimulation of the suprarenals and the secretion of adrenaline Nerve fibres to the spleen and suprarenal bodies are also carried in the nervus splanchnicus minor (I) Stimulation of these nerves produces sometimes both direct and indirect effects on the spleen and at other times only an indirect effect The authors failed to find nerve fibres from the nervus splanchnicus minor (II) running to either the spleen or suprarenal bodies J Barcroft L C Khanna and Y Nishimaru (ibid p 294) contest the view that the spleen has two essentially different rhythms a specific one with a period of a minute or more and a Traube Hering rhythm with a shorter period From experiments on cats they find that the period of splenic rhythm is between 25 and 50 seconds but when the spleen is in a bad condition or the general blood pressure is low the period of the rhythm is often over 60 seconds

406 Diagnostic Value of Leucocytosis and Red Cell Sedimentation

M M Reggiani (*Il Policlinico* Sez Chir February 15th 1932 p 104) has investigated the variation in the number of leucocytes and the velocity of red cell sedimentation in cases of appendicitis cholecystitis and abdominal anastomoses He concludes that no special characteristic value can be assigned either to the number of white cells or to the sedimentation rate of red cells in differentiating these three conditions There is no constant correspondence even in acute cases between the number of leucocytes and the sedimentation rate of the red cells Repeated examinations from time to time of the blood from the same patient during the infection showed that the increase in the leucocyte count was usually of short duration and was independent of the course of the illness the sedimentation rate on the other hand reflected with certainty the progress of the disease

407 Xanthoma Tuberosum

G H W Jordans and N van der Horst (*Nederl Tijdschr v Geneesk* February 27th 1932 p 967) who record three cases in patients aged 8 13 and 34 respectively state that hypercholesterinæmia has been found in most recorded cases of xanthoma and that its absence has been exceptional Until recently cholesterin formed the most important part of the xanthoma problem The present authors point out that it is not sufficient to examine the cholesterin metabolism only attention should also be paid to the neutral fats and other lipoids especially when hypercholesterinæmia is absent In their own cases there was a well marked disturbance in the metabolism of fats and lipoids but such a disturbance however is not sufficient to explain the formation of xanthoma In two of their patients the xanthoma appeared to be familial and in some members of their families the hypercholesterinæmia was apparently hereditary

THE 6 REQUIREMENTS OF THE PERFECT MOUTHWASH & GARGLE

★Requirement No. 2

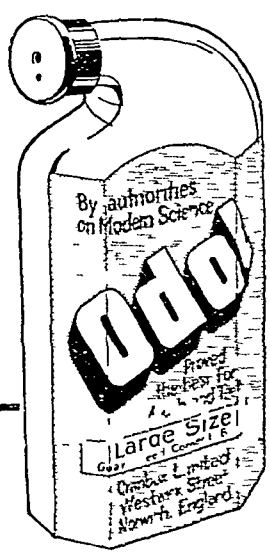
One of the outstanding virtues of Odol is that it wholly fulfils the second all-important essential of the perfect hygienic mouthwash, viz, it is non-irritant to the mucous membrane Odol is non-caustic, being perfectly non-injurious to the mucous membrane, and non-irritant Odol is peculiarly suited to the condition of the oral cavity, for its antiseptic is mild Odol is innocuous, and is promptly absorbed by the mucous membrane It is immediately effective where most wanted, i e, where fermentation and decomposition processes are taking place

All Six Requirements are fulfilled by

Odol

The Six Requirements

1 It must be absolutely harmless

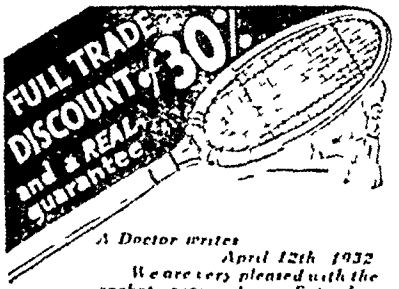


★2 It must be absolutely non irritant to the mucous membrane of the mouth

3 It must be definitely antiseptic

4 It must be neutral in reaction

5 It must be deodorising and refreshing



6 It must be agreeable to the taste

Samples and literature will be gladly sent to any member of the Medical Profession in the British Isles or the Irish Free State on request to Cranbux Ltd of Norwich

NO country in the world offers such a variety of natural mineral waters and spa treatments as are available in Great Britain At British Spas the staffs are educated and properly trained and, in most cases, medically trained and certificated Equipment and administration are thoroughly up-to-date and scientific.

British Spas are also remarkably fortunate as regards situation, scenic beauty and pure air These factors, combined with the social amenities of a home town, aid the cure considerably

Send your patient to a British Spa!

LEICESTERSHIRE COUNTY COUNCIL

MEDICAL SUPERINTENDENT

COMBINED COUNTY SANATORIUM AND FEVER HOSPITAL
(180 Beds—126 Tuberculous and 54 Fever)

The Leicestershire County Council invite applications for the appointment of a Medical Superintendent at their newly erected Combined Sanatorium and Fever Hospital at Markfield from registered Practitioners of not more than 45 years of age who have had extensive practical experience in the diagnosis and treatment of Pulmonary Tuberculosis and also of Infectious Diseases. It is also desirable that he should have executive and administrative ability and experience in the training of nurses for examination.

The salary attached to the appointment will be at the rate of £850 per year together with the use of an unfurnished house (rates and taxes) water light coal and laundry and will be subject to satisfactory service by biennial increments of £50 to £950. The salary is subject to a temporary reduction of approximately 5 per cent. The foregoing emoluments are valued at £150 per year.

The gentleman appointed will be required to devote the whole of his time to the duties of the office and the appointment will be subject to a present satisfactory medical certificate being provided and to the provisions of the Local Government and Other Officers Superannuation Act 1922.

The candidate appointed will be under the control and supervision of the County Medical Officer and will be required to furnish such advice and assistance appertaining to his office as may be required.

The appointment will be subject to three months' notice on either side and the successful candidate will be required to commence duties early in September.

Applications on the prescribed form obtainable from the undersigned and accompanied by copies of not more than three testimonials should be addressed to the undersigned and received not later than Monday May 23rd.

Canvassing of members of the County Council either directly or indirectly will be considered a disqualification.

10 New Street, Leicester. W. J. FREER, Clerk to the County Council.
April 23rd 1932

STAFFORDSHIRE COUNTY COUNCIL

BACTERIOLOGICAL AND PATHOLOGICAL LABORATORY

LABORATORY ASSISTANT

Wanted by the Laboratory Assistant Experience in the usual hospital routine. Practical Training will be given to those who have had satisfactory experience in general laboratory work.

Salary £220 per annum rising on satisfactory service by annual increments of £12 10s. to £250 subject to the usual deductions under the Local Government and Other Officers (Superannuation) Act 1922 and to a temporary cut which is at present £7 5s. on £220.

Applications together with copies of three recent testimonials to be sent to me not later than May 7th.

The appointment will be terminable by one month's notice on either side.

Court Buildings, Stafford. EUSTACE JOY, Staff Clerk.
April 22nd 1932.

HULME DISPENSARY, DALE STREET, Street East MANCHESTER

Wanted an HONORARY MEDICAL OFFICER. Application at once to the Hon. Medical Secretary.

LONDON COUNTY COUNCIL

Applications are invited for appointment to the position of RESIDENT ASSISTANT MEDICAL OFFICER (men only) at the undermentioned hospital.

Duties will be of a general nature as assigned by the medical superintendent and include if necessary assistance at the establishment under the control of the Council.

Remuneration in each case subject to temporary reduction. Candidates must be duly qualified Medical Practitioners of at least one year's standing and have held a resident appointment in a general hospital for six months.

SHOREDITCH HOSPITAL, Hanbury Hill, S.E.10 — ASSISTANT MEDICAL OFFICER (Grade I). Salary £350 a year rising by annual increments of £25 to £425 a year together with board lodging and washing.

CONSTANCE ROAD INSTITUTION, Dulwich, S.E.22 (under the control of the Medical Superintendent of Dulwich Hospital) — ASSISTANT MEDICAL OFFICER (Grade II). Salary £250 a year together with board lodging and washing. Appointment for one year only.

Applications also invited for appointment to the position of RESIDENT ASSISTANT MEDICAL OFFICER (Grade II (men only)) at SHERRARD HOSPITAL, Lovegrove Walk (210 beds) for Non-pulmonary Tuberculosis Cases (male and female adult). Light treatment and X-ray facilities.

Remuneration (subject to temporary reduction) is £350 a year rising by annual increments of £25 to £425 together with board lodging and washing. Candidates must be duly qualified Medical Practitioners of at least one year's standing. Experience in a resident appointment in a general hospital and of the treatment of tuberculosis is desirable.

Forms of application obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division 3a), County Hall, Westminster Bridge, S.E.1 not later than May 6th. Canvassing disqualifies. Further inquiries should be addressed to Medical Superintendent at the Hospital.

URBAN DISTRICT COUNCIL OF STRETFORD

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER

Applications are invited for the appointment of Assistant Medical Officer of Health and Assistant School Medical Officer to carry out medical inspection and treatment of school children and to attend at Maternity and Child Welfare Centres and Ante-natal Clinic and generally to assist in the work of the combined Health Service of the district under the direction and supervision of the Medical Officer of Health and School Medical Officer.

Candidates should have had at least three years experience in the practice of the profession and special experience of practical midwifery and ante-natal work. Experience in infectious diseases and in children's diseases desirable.

The salary will be at the rate of £500 per annum rising by annual increments of £25 to a maximum of £700 subject to a temporary percentage deduction in accordance with the scale approved by the Council. The appointment is subject to the provision of the Local Government and Other Officers Superannuation Act 1922 and the successful applicant will be required to pass a medical examination.

Application must be made on forms to be obtained from the Medical Officer of Health, Council Office, Old Trafford, which should be completed and forwarded together with copies of three recent testimonials not to reach the undersigned not later than May 7th.

Canvassing of any description will be deemed a disqualification.

Council Offices, Old Trafford. CECIL H. ABRAHAMS, Clerk to the Council.
April 1932

COUNTY OF LONDON

The LONDON COUNTY COUNCIL invite applications for appointment as ASSISTANT MEDICAL OFFICER (rising) under 35 years of age in Mental Hospital Service. Candidates must be registered practitioners in Medicine and Surgery in England, must be of at least five years' professional standing and must have held a residential position in a general hospital for six months or have had equivalent experience. Salary (subject to temporary reduction) £475 a year rising to £550 a year (additional allowance £50 a year to holders of D.P.M.). No emolument at present (£2 9s. a week) if required to be provided. Small uniform allowance. Superannuation Act 1909. Application form giving full particulars to be obtained from Chief Officer (I.A.B.), Mental Hospitals Department, Artillery House, Artillery Row, S.W.1. Application must be received not later than May 14th. Canvassing disqualifies.

WANTED — HOUSE SURGEON (MALE) for Hospital, County Hospital, Hereford. Salary at £125 per annum, at present all found. Apply Senior Medical Officer.

CITY OF LIVERPOOL

MEDICAL SUPERINTENDENT

ALDER HEY CHILDREN'S HOSPITAL.

Applications are invited from fully qualified Medical Practitioners, who possess administrative and experience of Hospital administration, for the appointment of Medical Superintendent at the above Hospital at a salary of £1,000 per annum together with allowances of £150 per annum in lieu of rooms, subject to temporary reduction as at present in the Council. All services rendered in connection with the appointment to be rendered exclusively to the City Council.

The gentleman appointed will be required to reside in the Hospital under the direction of the Medical Officer of Health and Hospitals for the work of the Medical Nursing and Administrative Staff in accordance with the instructions of the Council from time to time.

The Hospital which has been approved under the Public Health Acts from April 1st next has accommodation for approximately 450 patients with a Resident Staff of Assistant Medical Officers and Visiting Specialists and a Nursing Staff of 250. Provision is made for the treatment on modern lines of all classes of acute children's diseases medical, surgical and orthopædic including surgical tuberculosis and considerable experience of children's ailments is essential. The Hospital is recognised by the General Nursing Council as a Training School for Sick Children's Nurses and the Medical Superintendent will be required to organise the necessary lectures in connection with the training.

The appointment will be made subject to the Local Government and Other Officers Superannuation Act 1922 and the Standing Orders of the City Council and will terminate at three calendar months' notice on either side. Further information concerning the terms of appointment may be obtained upon application to the Medical Officer of Health.

Application upon forms to be obtained from the Medical Officer of Health, Municipal Annexe, Liverpool, giving full particulars as to age, qualifications, experience, together with copies of testimonials, should reach the undersigned not later than Saturday, May 21st.

Canvassing of Members of the City Council either directly or indirectly will be regarded as a disqualification.

Municipal Offices, Liverpool. WALTER MOON, Town Clerk.
April 25th 1932

CITY OF LIVERPOOL

PATHOLOGIST

Applications are invited for the appointment of full-time Pathologist for certain of the Corporation Hospitals at an inclusive salary of £700 per annum subject to a temporary deduction authorised by the City Council. Any fees received in connection with the appointment to be handed over to the City Council.

Candidates, who must be fully qualified and registered, must have specialised in Pathology and Bacteriology and have had considerable experience in a recognised pathological department.

The gentleman appointed will be responsible for supervising the work of the different laboratories and will be required to co-operate generally with the medical staff so far as this particular service concerns.

Forms of application and particulars of the duties may be obtained from the Medical Officer of Health, Municipal Annexe, Liverpool.

The appointment will be made subject to the Local Government and Other Officers Superannuation Act 1922 and the Standing Orders of the City Council and will be terminable by three calendar months' notice on either side.

Application and Testimonials to be forwarded to the undersigned not later than Saturday, May 14th.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(Founded 1880)

12, Stratford Place,
Oxford Street, W.1

Tele. Address: Triform, Wesdo, London. Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices or desiring to take Partners are advised to entrust the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal supplied gratis to Purchasers.

ASSISTANTS AND LOCUM TENENS

Assistants and Locum Tenens can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY

The British Medical Bureau has its own staff of qualified Accountants wholly engaged on medical work. Investigations of Practices for purchasers. Income Tax. Auditing Accounts, etc.

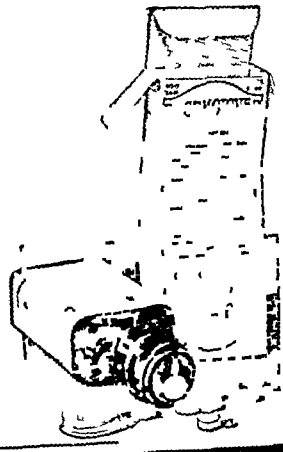
AMENORRHEA

The most successful treatment is that which supplies the endocrine stimulus to menstruation

Prescribe



HORMOTONE

BRAND

The clinical use of Hormotone has now extended over a long period of years and its success has been thoroughly demonstrated. In scanty menstruation or actual suppression of the menses it is an effective therapeutic agent.

Dose 1 or 2 tablets three times daily

Bottles of 100 tablets

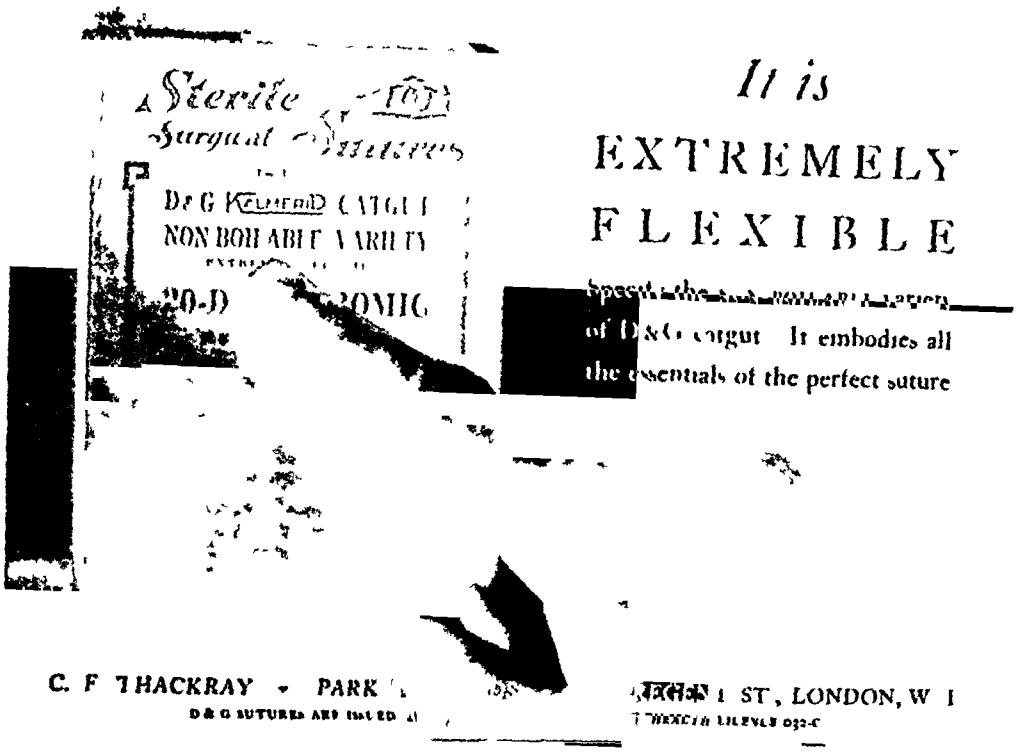
"Trade **Pitibulin** Mark"

Denotes Unvarying Pituitary Extract



Conforming to the requirements of the Therapeutic Substances Regulations, 1927, 'Pitibulin' is prepared according to the official standards its activity being expressed in terms of the accepted unit. 'Pitibulin' maintains the stringently high criteria of therapeutic efficiency, safety in use and stability self imposed by its manufacturers—qualities which have given it its high place in the esteem of physicians. It has made a reputation among the Profession as the Pituitary Extract which can be relied on in emergency.

Pitibulin is supplied in boxes of 6 and 12 ampoules, containing 1 c.c. and 2 units per ampoule.

Literature containing full particulars of the therapeutic uses of Pitibulin will be sent on request.

Allen & Hanburys Ltd.,

London, E.2.

The Therapeutic value of BRANDY—

its lifting and sustaining powers—as compared with other spirits depends on the presence or absence of the higher Alcohols or Ethers These in turn depend on Grape, Soil, Stills employed, Climate, Storage, Selection and Experience

It is quite easy to make a spirit from grape wine—It is neither easy nor cheap to make a Brandy containing the qualities you want.

Cognac Brandy alone provides them

Take no risks; ensure the results you expect

Prescribe Brandy distilled in Pot Stills from Wines grown in the best Cognac districts, Matured in warehouses which have been filled with Cognac Brandy for centuries, Made by Men with the inherited Experience of Seven Generations

In short—Prescribe MARTELL'S BRANDY

and know that you are doing the best possible for your patients

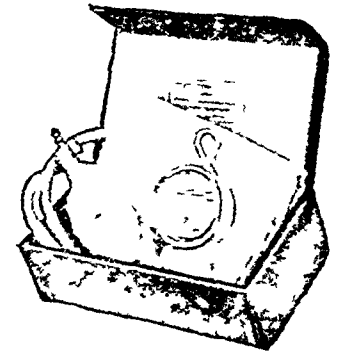
IS IT FAIR to your best friend to make him your Executor? The duties are onerous, and usually thankless, the responsibilities are great and the penalties for neglect are severe Moreover, he may die, and the expense of appointing his successor is considerable On the other hand, if you appoint the Westminster Bank instead, the fees (which are paid out of your estate) will probably be only a fraction of the legacy which you would have left to a private trustee



Ask for the Executor and Trustee booklet at any local branch, or call at

Candidly Speaking!

"I'm not going to pretend," said the Vicar, "that I have not smoked other tobaccos than Three Nuns, sometimes when away in the wilds one has had to wait for supplies And I'm not going to pretend that some of those others have not been good tobaccos of their kind But oh, the blessed relief of getting Three Nuns again! The joy of releasing the fragrance immured in those mellowed discs! The little extra it costs me I get back in full, because a pipe of Three Nuns lasts so much longer than a pipe of any other tobacco I've tried"

THREE NUNS

the tobacco of curious cut—1s 2½d an ounce

A LETTER TO THE MEMBERS OF THE MEDICAL PROFESSION

We have received thousands upon thousands of letters from established doctors testifying to the medical value of The Doctor's China Tea. For obvious reasons we never publish any of those letters but if we were at liberty to do so they would form an overwhelming argument in favour of The Doctor's China Tea in cases of dyspepsia and other gastric troubles. As one doctor (a confirmed dyspeptic) writes— **This tea is an absolute boon to me**

The Doctor's China Tea has achieved this reputation among medical men—and the general public—because it is free from excess tannin. Because it is not only delicious but also harmless—even to the most delicate digestion. The Doctor's China Tea is the only tea thousands upon thousands of people can drink. It is the only tea that thousands upon thousands of doctors use themselves and recommend to their patients and to expectant mothers. We would like to have your opinion upon our product. May we send you a free ¼ lb. packet?

Yours faithfully

For and on behalf of

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl salicylic acid possesses a notable disadvantage Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced

Alasil completely overcomes this objection By combining calcium acetyl salicylate with Alocol unfavourable secondary action upon the stomach is prevented This beneficial influence is undoubtedly due to the presence of Alocol (Colloidol Hydroxide of Aluminium) which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract Alasil is therefore a triumph over acetyl salicylic acid It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time Analgesic Antipyretic and Sedative Alasil is indicated in all cases where acetyl salicylic acid has been used heretofore

A supply for clinical trial with full descriptive literature sent free on request

Alasil

Injection treatment of

Varicose Veins

" this form of treatment has become an accepted standard procedure, widely used by the general practitioner and favoured by the progressive surgeon " (J. Am. Ass. Med. Jour., 1931)

In the injection treatment of varicose veins Sodium Morrhuate B.D.H. has been employed with remarkable success

Sodium Morrhuate B.D.H. consists of the sodium salts of the purified unsaturated fatty acids extracted from cod liver oil. It forms a light amber coloured soapy solution in water

Sodium Morrhuate B.D.H. possesses many advantages. The technique of injection is simple, there are no toxic after effects, and whilst the pain is slight it produces sufficient irritation to cause the desired endothelial damage

Sodium Morrhuate B.D.H. is issued in a 5 per cent. and a 10 per cent. sterile solution and is available in ampoules and in rubber capped vaccine bottles

SODIUM MORRHUATE B.D.H.

HORLICK'S MALTED MILK

in Digestive Disorders

In diseases and disorders of the gastro-intestinal tract—gastric and duodenal ulceration, acute and chronic gastritis—it is essential that the diet should be bland and soothing. The food should be in a fine state of division and care must be taken to avoid constituents which may irritate the mucous membrane. *Horlick's Malted Milk* is constantly being recommended for use in these conditions. Composed of full-cream cows' milk combined with the soluble extracts of malted barley and wheat, it meets the requirements of both doctor and patient, since it contains nothing to cause mechanical irritation or to excite a secretion of mucus. It is easily prepared and permits meals of small size at frequent intervals to be taken by the patient in an agreeable and palatable form. *Horlick's* is also an excellent vehicle for the addition of other articles such as eggs to the dietary. *Horlick's Malted Milk* has also been used with marked success in epidemic diarrhœa and dysentery.

Points of Perfection in the Preparation of LACTOGEN

Digestibility

The preparation renders the curd of Lactogen exceedingly light and flocculent, very similar to that of breast milk The emulsification of the fat reduces the globules to a very fine state of division Both these factors contribute to the ease with which Lactogen may be digested by even the most delicate infant Lactogen is a modified dried milk for use in infant feeding—prepared in England by Nestlé's, from the rich, pure milk of selected English herds

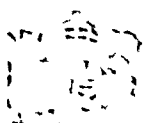
Palatability matters a great deal in invalid diet

FOODS LIKE THESE INTEREST AND ATTRACT EVEN THE MOST ATONIC STOMACH

Palatability is often the determining factor in correct dieting — especially during severe illness. The more difficult it is for the patient to accept a food the less digestible that food will be. All the doctor's skill is needed to suggest just those foods the patient is likely to find most palatable.

The extreme palatability of Brand's Invalid Foods is something every generation of medical men for 100 years has recognised. Brand's Real Calf's Foot Jelly, Brand's Meat Juice, Brand's Invalid Soups, as well as the famous Meat Essences. They stimulate the appetite and re-awaken interest in food.

No need to recommend foreign Meat Juice and Calf's Foot Jelly — Brand's Invalid Products are BRITISH — made from the finest freshly-killed English meats. And they are all sterilized.



BRAND'S MEAT JUICE

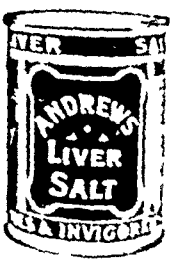
HAY FEVER

Detoxicated Anti-Coryza Vaccine (Genatosan) has proved a successful prophylactic with many patients previously subject to annual attacks of hay-fever. As this vaccine is detoxicated, massive doses may be administered with little or no reaction.

In actual treatment, and also for prophylaxis with hypersensitive and nervous patients, local application of Anti-Coryza Spray Vaccine is indicated.

Additional information regarding the above products will gladly be supplied to any Practitioner who writes to The Vaccine Department, Genatosan Ltd., Loughborough, Leicestershire



A useful Saline Aperient

Andrews Liver Salt is an ideal Saline aperient of pleasant taste, readily taken and well tolerated by the most delicate adult or child. It ensures an easy and complete evacuation without griping or tenesmus, it is not contra-indicated in the majority of diseases where constipation arises.

It acts by stimulating the intestinal glands, thus increasing the fluid content of the bowel, producing gentle peristaltic contractions and a natural and efficient clearance of the colon and rectum without any unpleasant after effects.

In cases of fever, its brisk effervescing solution in water makes a refreshing and invigorating drink, relieving thirst, diluting the toxins and relieving the strain upon the kidneys.

It may be used as a hydragogue purgative in the treatment of oedema ascites, pleuritic effusions and nephritis, and with safety even in failing cardiac conditions.

Andrews Liver Salt

The "Jack Spratt" Child

"Jack Spratt could eat no fat"

THERE are many children who digest fat badly Almost every child with a nervous temperament is a "Jack Spratt," a fact that has been emphasised lately by such eminent authorities as Still Cameron and Orman

Nervous condition In childhood tend inevitably to increase under the conditions of modern life They manifest themselves by frequent bilious attacks constipation cyclical vomiting loss of appetite and general digestive difficulties

Nervous children cannot tolerate a diet rich in fat and such fat as are present in their food must be more than abolished in an excess of sugar

To meet the needs of this type of infant the manufacturers of COW & GATE MILK FOODS have provided a Half Cream Milk Food the composition of which is given below It has been used in the wide range of nervous dyspepsias of infancy with eminently satisfactory results

Members of the Medical and Nursing Professions are further advised that a special *unmodified* Half Cream Milk Food is also available Samples and the fullest possible information will gladly be supplied

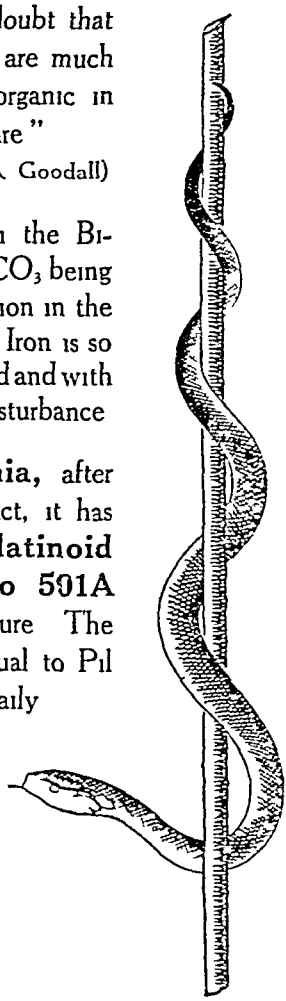
THERAPEUTIC NOTES

from

Oppenheimer Son & Co Ltd



ANAEMIA:

"In Chlorosis there is no doubt that the inorganic forms of Iron are much more efficacious than the organic in bringing about a speedy cure"

The Blood (Gulland & Goodall)

This fact is accentuated in the Bipalatinoid owing to the Fe CO_3 being formed in the nascent condition in the stomach No other form of Iron is so readily and rapidly assimilated and with so little digestive or other disturbance

In Pernicious Anaemia, after treatment with Liver Extract, it has been found that **Bipalatinoid Ferrous Carb,** gr iii, **No 501A** will maintain the blood picture The dose is 3 Bipalatinoids (equal to Pil Blaud gr 15) three times daily

Exempla:

BIPALATINOID No 500
Ferrous Carb gr i = 1 Pil Blaud

BIPALATINOID No 511

HANDFORTH LABORATORIES — CLAPHAM ROAD — SW 9

GASTRIC FABLES

A TALE OF DOMESTIC HAPPINESS

She was a nagging nervous wife, he a raging irritable husband They were told it was 'all a question of diet' If the human animal is *properly fed*, he—or she—is likely to be amiable and easy going

So he went on a three months' cure where fasting "alternated with carrots salads, golden maize meal porridge and plenty of milk' She too undertook a three months' rest and 'a diet of cream, honey and raisins'

After three months they reunited, he more generous and less ferocious she more docile and angelic. When regular food again threatened to disturb their domestic happiness, their physician recommended less drastic measures and prescribed CAL-BIS-NATE

A wise physician, he knew that the suffering from gastric hyperacidity is likely to disturb the most amiable disposition Instead of a freak diet, regulation of the stomach function is the rational remedy

Cal Bis Nate is a combination of calcium and magnesium carbonates, sodium bicarbonate, bismuth and colloidal kaolin, blended into a palatable powder It neutralizes excess gastric

acidity quickly efficiently and with lasting effect We will gladly explain the therapeutic merits of Cal Bis Nate and send a professional trial package for the asking Send for it

COSTUME IN WHICH PHYSICIANS AND OTHERS IN EARLY AND LATE RENAISSANCE TIMES VISITED THE PLAGUE-STRICKEN.—The Venetian Republic was the pioneer European state to take measures to check the spread of the "Black Death" when North Italy was attacked by it in 1348. Three guardians of public health were appointed, quarantine *(quarinta giorni)* was established, and instructions for public and personal hygiene were issued. Later, a lazaret was built on an adjacent island. These measures

opened the campaign against epidemic diseases. Among the precautions recommended against the Plague were the burning of incense and camomile. The costume here illustrated, is from a treatise on the Plague: it was made of leather, which because of its odour, was held to be capable of resisting the plague poison." The nose formed like a beak, is anointed with various balsams and filled with aromatics and drugs with which the air passing through a hole on either side becomes impregnated before reaching the body. The eye openings have windows of crystal: the hat boots, trousers and gloves are also of leather.

Date A D 1348-c 1600. The figure 1656 but the costume originated much earlier.

HYPOTENSYL

Opocrin Brand TABLETS

The active principles of Viscum (Gui) with Gland Extracts for the treatment of conditions associated with

HIGH BLOOD PRESSURE.

Hypotensyl is available in tablet form, each tablet representing

Viscum Album Extract	0 075 Gm
Hepatic Extract -	- 0 10 "
Pancreatic Extract -	- 0 05 "

Dosage From 3 to 6 tablets daily before meals
Supplied in bottles of 50 tablets

Literature and samples on request from—

ON

THE SURGICAL TREATMENT OF INTRATHORACIC NEW GROWTHS*

BY

A TUDOR EDWARDS M.D. M.CHIR. F.R.C.S.

SURGEON TO THE BROMPTON HOSPITAL; SURGEON TO OUT-PATIENTS WESTMINSTER HOSPITAL

(With Special Plate)

Reports from the Continent and from the United States of America now contain a considerable number of cases of both benign and malignant tumours arising within the thoracic cavity. It is probable that the apparent increase in benign neoplasms is entirely due to improved methods of diagnosis more especially the increased frequency of radiological examination but there appears to be still some doubt as to whether there has been an absolute increase in the numbers of cases of malignant disease. In the latter the relative increase is accepted by all observers. The most significant record as regards malignant neoplasms is that produced by Rosahn who has collected records of a large number of total necropsies from varying sources. In 86,824 post mortems performed during the period 1910–19 pulmonary carcinomas comprised 0·44 per cent. of all necropsies and 4·39 per cent. of all cancers whereas in 50,308 from 1920 to 1928 pulmonary carcinomas comprised 0·89 per cent. of all necropsies and 6·98 per cent. of all cancers. From these figures Rosahn infers that the (post mortem) incidence of primary carcinoma of the lung is steadily increasing and this increase is real and absolute.

The intrathoracic tumours may be divided into three main groups—the pleural, the mediastinal, and the pulmonary—and from the pathological point of view these can be subdivided into benign and malignant types.

BENIGN PLEURAL TUMOURS

The great majority of tumours described as pleural arise in tissues adjacent and as they increase in size tend to project into the pleural cavity being covered by the parietal pleura. In this manner fibroma, lipoma, chondroma, ganglion, neurofibroma, and compound tumours of these types arise in the extrapleural tissues. These tumours are often symptomless until they have reached considerable size. Perhaps the most common symptom is pain which is quite localized and persistent. Occasionally an irritating cough is present but is rarely accompanied by expectoration. The physical signs consist of an area of localized dullness on percussion with relative diminution or absence of breath and voice sounds. In some cases there may be evidence of an external tumour of the chest wall and this is most likely to occur in the chondromas and in the ganglion neurofibromas. In the latter there may also be evidence of involvement of the sympathetic chain on the same side as shown by eye signs—enophthalmos, etc.—the so-called Horner's syndrome. Effusions are rare in the benign growths.

The diagnosis is confirmed by radiological examination which will determine the extent of the tumour and will show well-defined outlines. The production of artificial pneumothorax will generally differentiate these tumours from those arising in the lung itself, as in the former case the lung will collapse and retract towards the hilum leaving the tumour in its former position. Early surgical removal is advisable if the general condition of the patient permits. Naturally the larger the tumour the more serious the operative risks, but it is well to remember that benign tumours within the thorax tend to encroach upon vital structures and thereby destroy life, and that many of these tumours are potentially malignant.

MALIGNANT PLEURAL TUMOURS

Primary endothelioma and sarcoma occasionally arise from the pleura or again from the structures immediately adjacent. Endothelioma may be localized or diffuse, but the latter type is the more common, the growth forming either a large thick plaque fusing lung and pleura or being spread over the visceral and parietal pleural surfaces which are generally separated by a pleural effusion. This is serous in the early stages but is almost invariably haemorrhagic later. In these cases the first symptoms to arise are either localized pain or marked dyspnoea. The former is more common in the localized tumour and may give rise to suspicions of abdominal disease owing to the reference of the pain along the intercostal nerves to the abdomen. In the diffuse type dyspnoea owing to the large effusions is often the first evidence of chest disease. Secondary glands in these conditions may sometimes be felt in the supraclavicular area or on the inner wall of the axilla.

Aspiration of the fluid and its replacement by oxygen or air followed by radiological examination will then enable one to see the irregular growth on the surface of the pleura. In cases where this cannot be seen introduction of a thoracoscope under local anaesthesia will enable one to visualize the growth. Sarcoma may arise as a localized mass in the chest wall involving the pleura. It can only be distinguished from the localized endothelioma by histological examination.

Surgical treatment is only to be considered in the localized types but owing to late diagnosis this is rarely possible. In one patient an endothelioma was localized sufficiently for radical operative treatment but in this case the involvement of the mediastinal and supraclavicular glands negatived operation. In the diffuse form deep x-ray therapy or the application of a large radium plaque or a combination of both methods is the only means of treatment likely to offer any form of alleviation.

BENIGN MEDIASTINAL TUMOURS

Benign tumours in the mediastinum consist of (1) the intrathoracic goitres and (2) dermoids and teratomas.

In the superior mediastinum the *intrathoracic goitre* is the most common. It may be associated with an enlarged thyroid in the neck or with an apparently normal thyroid gland in that situation; it may be solid or cystic and is occasionally calcified. In some cases there may be a history of a goitre in the neck some years before which has disappeared. These tumours of course are distinct from goitres which are sometimes situated in the neck and sometimes displaced into the mediastinum and which have been termed "plunging goitres."

The most characteristic symptom is dyspnoea which may be persistent or intermittent. In two patients submitted to operation for this condition asthma had been diagnosed and treated for several years. In the larger tumours there is often evidence of interference with the venous return to the heart resulting in cyanosis of the skin of the head and neck and considerable dilatation of the veins of the neck and of those overlying the sternum. This appearance often gives rise to suspicions of malignant disease of the mediastinum. Where the goitre is of the toxic type there will be superadded signs of hyperthyroidism. Physical signs consist in the presence of an area of dullness on percussion over the sternum corresponding in extent to that of the tumour.

Radiological examination will show a well-defined opacity in the superior mediastinum. Lateral skiagrams

* Delivered before the Bath Bristol and Somerset Branch February 1932.

are of limited value only in this position but an oblique view will help to localize the site of the mass. Almost invariably there is considerable deviation of the trachea from the normal position to one or other side but in three cases marked forward deviation of the trachea by a retrotracheal mass has been seen. Screen examination may show movement of the mass upwards on deglutition a sign which may distinguish this type of growth from other varieties of mediastinal tumour.

Mediastinal thyroids should invariably be removed by surgical operation as soon as they give rise to any symptoms. Hæmorrhage into the tumour is quite likely to cause sudden respiratory obstruction and therefore this danger should be avoided by early operation. The tumours are approached through the usual collar incision in the neck. After careful separation by blunt dissection with the finger from the surrounding tissues they can be dislocated in the neck. In very large tumours however it may not be possible to obtain sufficient room to deliver them through the superior aperture of the thorax and in such cases splitting of the sternum in the middle line down to the third space together with a transverse incision outwards will allow adequate exposure. In eleven cases of intrathoracic goitre the sternum splitting extension was necessary on three occasions.

Illustrative Case I

Man aged 42 admitted to hospital on May 11th 1927 complaining of cough and shortness of breath from which he had suffered for twenty years. A small amount of expectoration was present with occasional hæmoptysis. From January 1925 to April 1926 he was in one of the London infirmaries where a diagnosis was first made of pleurisy then of a malignant mediastinal tumour thought to be inoperable. He had gained nearly 2 st. in weight between his discharge from the infirmary and his admission to hospital. On examination he had a large mass of dilated veins overlying the upper chest with congestion and cyanosis of the veins of the neck. The left pupil was larger than the right but both were active. He had slight ptosis of the right eye which was said to have been present for ten years.

Radiological examination showed tumour in the superior mediastinum (Figs. 1 and 2 on Plate).

Operation was performed on May 18th 1927 the sternum being split in the middle line down to the third intercostal space and outwards into the intercostal space on each side. The tumour was carefully freed from the surrounding tissues and removed the only trouble being a large vein in the posterior part of the capsule which bled freely. The sternum was sutured with silk.

The subsequent history was uneventful except that one of the silk sutures became infected and had to be removed.

Dermoids and Teratomas

These are tumours which rarely cause symptoms due to their mediastinal position but tend to dissect outwards between the lobes of the lung. They may arise in the anterior or the posterior mediastinum and in the latter case tend to pass up in close relationship with the superior vena cava on the right or the arch of the aorta on the left. Two groups of symptoms may be encountered in these tumours. In the first group symptoms are absent until the mass reaches the parietal pleura whereupon they give rise to pain and dyspnœa similar to that encountered at the onset of an attack of simple pleurisy. The associated physical signs will be dullness on percussion and absence or diminution of breath sounds. In the second group the symptoms are associated with irritation of the bronchus due to the pressure upon and possibly later to rupture of the cyst into the bronchus. Irritation of the bronchus causes a non productive cough often with few physical signs. Later perforation of the bronchus may result and portions of the cyst contents (that is hair or sebaceous material) be expectorated. Secondary infection of a ruptured cyst will result in fever and expectoration of offensive purulent sputum. Continued pressure on the bronchi will lead to partial obstruction and the development of secondary bronchiectasis.

Radiological appearances will vary in accordance with the size of the tumour but in most cases except those infected, the outline of the tumour is clearly defined often rounded or oval while in a certain proportion teeth and bone may show as denser opacities. After pneumothorax skiagrams will show the tumour buried in the collapsed lung.

The treatment is the same as that in other benign tumours—that is operative removal. Apart from the results of pressure on bronchi vessels and nerves secondary malignant changes occasionally supervene. In certain instances the diagnosis can only be made by exploratory thoracotomy and in two cases in which carcinoma was diagnosed previous to operation teratomata have been successfully removed with complete recovery of the patients. These tumours should be explored by transpleural incision either anteriorly or posteriorly according to the site of the tumour. Of twelve patients operated upon for these tumours complete recovery followed removal of the tumour in eight. One case showed malignant changes at operation although it was known that the patient had had a tumour in the mediastinum for several years previous to operation. Judging from examination of the skiagrams the alteration in this tumour had occurred within the previous few months.

Illustrative Case II

Girl aged 19 admitted to hospital on May 27th 1929 with a history of cough headache substernal pain and shortness of breath which had been present for two years. There was no expectoration. Examination showed an area of dullness over the right chest posteriorly and anteriorly with weak breath sounds over the same area.

Radiological examination showed a dense homogeneous opacity at the upper part of the right apex. In the lateral plane the opacity appears to be posteriorly (Fig. 3). After pneumothorax the upper border of the opacity was well defined and the tumour was shown to be extrapulmonary (Fig. 4).

An exploration was carried out posteriorly. At this operation June 12th 1929 a posterior incision was made between the fifth and sixth ribs a very small portion of each being removed. A large thin walled cystic tumour was then seen to be lying in the upper post medial part of the pleural cavity and extending into the posterior mediastinum. The wall of the cyst was completely covered with a network of dilated veins. On account of this the cyst was marsupialized and drained.

At the second operation September 11th 1929 the chest was reopened and it was found that the cyst wall was much less vascular. The whole of the cyst wall was then separated by a careful dissection and removed as a complete sac. Apart from the aspiration of about 10 ounces of blood stained fluid from the pleural cavity three days later convalescence was steady. On November 12th 1929 an excision of the wound edges was performed and two little pockets apparently lined with smooth membrane were dissected free and a third which was in close contact with the vessels was swabbed with pure carbolic in order to destroy the lining membrane. Drainage was carried out and after several months healing took place. The patient is now free from symptoms.

Malignant Mediastinal Tumours

Lymphosarcoma and lymphadenoma are encountered in the mediastinum. The former disease is much more rapid in onset and growth and in development of symptoms. In both conditions enlarged glands are often found in the neck and axillæ. In the case of lymphadenoma enlargement of the spleen and occurrence of Pel Ebstein temperature crises may serve as diagnostic factors. Enlarged glands when present should be removed for histological examination. Operation on these cases is rarely possible

or advisable and in only one case has it been possible to remove a large mass in this situation This subsequently proved to be a primary lymphadenoma of the thymus and the patient died fourteen months later from generalized lymphadenomatosis In these cases both lymphadenoma and lymphosarcoma deep x ray therapy appears to be definitely indicated and in many cases the mass completely disappears following this treatment In many recurrence takes place and appears to be much more resistant to the action of the rays than does the original tumour

Benign Pulmonary Tumours

These are relatively very rare and it is probable those tumours described as chondroma and osteoma of the lung are really teratomata which have arisen in the mediastinum and subsequently insinuated themselves between the lobes becoming firmly adherent to the lung tissue One or two cases of fibroma arising in the bronchi have also been described Hydatid cysts are relatively common in the lung in certain countries and surgeons in Australia and the South American States have recorded considerable numbers These cysts are either single or *multiple and may* be completely silent as regards symptoms or signs Patients with hydatid disease run the risk of rupture of the cysts into the pleura when they are peripheral or into the bronchi when they are central In the former case there is a very acute local and general reaction whereas in the latter the sudden flooding of the bronchi by the cyst fluid may result in drowning of the patient If the immediate rupture is survived the cyst tends to become infected and gives rise to signs similar to pulmonary abscess

Radiological examinations show a characteristic appearance—a rounded or oval shadow with practically no reaction in the form of consolidation in the surrounding lung The diagnosis can be confirmed by the cutaneous and complement fixation reactions

The peripheral cysts should be removed and this can be done in one or two stages If done in one stage the surrounding lung should be marsupialized to the chest wall before the cyst is opened and removed Where the cysts are central unless complications supervene operations are contraindicated

Malignant Pulmonary Tumours

Primary carcinoma may originate in the large bronchi the bronchioles or the alveoli It is most commonly encountered in the larger tubes the primary bronchi and these neoplasms are mainly of two *histological* types—squamous celled and cuboidal acinar type The former probably arise as a result of metaplasia of the lining cells and the latter often show mucoid changes suggesting their origin from the mucus forming cells of the mucosa The more peripheral carcinomas are commonly squamous celled but rarely endotheliomata appear to arise in the lung possibly from cells lining the small vessels or lymphatics Lung carcinomas appear to be symptomless often for considerable periods but dyspnoea seems to be one of the earliest and most predominant symptoms In other cases a small haemoptysis may be the earliest sign to be followed by a febrile attack often diagnosed as influenza The later symptoms vary In some patients an effusion develops in others symptoms of bronchiectasis such as cough and expectoration Occasionally pain may predominate in the picture In those carcinomas arising in the larger bronchi atelectasis of a portion or a whole lobe may be the cause of such physical signs as are present The diagnosis may be confirmed by the introduction of lipiodol which will show an irregular obstruction partial or complete in the involved bronchus in the skiagram subsequently taken In obstructions of the main bronchi bronchoscopy with removal of a portion of the growth will make the diagnosis certain In the more peripheral carcinomata haemoptysis may be the only evidence of any abnormality in the lung In other cases a persistent cough may be present

Radiological examination shows an irregular opacity in the lung without evidence of any surrounding lung reaction or a fan shaped shadow apex at the hilum corresponding to the atelectatic area In the more advanced cases enlarged glands may be present in the neck or axillae These when present should be removed under local anaesthesia for histological examination

Carcinoma arising in the larger bronchi rarely allows of radical extirpation owing to its position and to the common involvement of mediastinal glands at the time when the condition is diagnosed Papilloma showing early malignant changes have been successfully removed through a bronchoscope On two occasions it has been possible following thoracotomy successfully to remove tumours arising in the larger bronchi One of these arose in the upper lobe of the left lung and proved to be a low columnar celled carcinoma the other a squamous celled carcinoma arising in the main bronchus to the middle *lobe of the right lung (In this patient the middle lobe* was removed) Both patients are completely free of symptoms one two years the other thirteen months after operation

Carcinoma arising in the alveoli and smaller bronchi offers greater opportunity for radical operation but these tumours are more rare than the previous type

The treatment of primary carcinoma by deep x ray therapy is disappointing and it is doubtful if even temporary improvements can be obtained Similarly radium as a massive application or in the form of a plaque applied to the surface has been disappointing The most encouraging results have been obtained by the use of radon seeds introduced into the growth or in its neighbourhood In those carcinomas arising in the *main bronchi* the seeds have been placed in a special container and this has been introduced into the affected bronchus through the bronchoscope It is retained *in situ* for varying periods between five and eight days By these means complete disappearance of the intrabronchial growth has resulted in several cases but the ultimate result is yet to be determined as this method has only been used for about three years

Illustrative Case IV

Woman aged 50 admitted to hospital on September 19th 1930 with a history of bronchitis in January of the same year and *with cough persisting subsequently* Some pain in the left chest and one small haemoptysis early in the present year Some dyspnoea and lost in weight Examination showed dullness and bronchial breath sounds over the upper two thirds of the left lung

Radiological examination showed the right lung to be normal and the left lung to be densely opaque in all zones (Fig 7) Lipiodol showed almost complete obstruction of *the left descending bronchus* Bronchoscopy was performed and the growth was seen immediately below the bifurcation of the trachea in the left main bronchus A portion removed for examination showed it to be a squamous celled carcinoma On December 3rd 1930 a radon container was inserted holding eight 1·8 millicurie seeds This was retained for eight days The patient was admitted on February 11th for further examination Bronchoscopy on this date showed the mucous membrane at the site of the previous growth to be smooth and of normal colour there being no obvious diminution of the lumen but a small valvular flap located 1 inch below which was easily dilated with a bougie X ray appearances of the patient afterwards are shown in the skiagram (Fig 8)

Where the growth cannot be seen by the bronchoscope open exploration of the chest is undertaken and the radon seeds are inserted into the growth under direct vision By this means also several satisfactory results have been obtained

ILLUSTRATIVE CASE III

Woman aged 65 seen on November 19th 1931 with a history of feeling run down and poorly since November 1930 In August 1931 she had an attack of bronchitis associated with pain in left side of chest and shoulder pain becoming much more severe Physical examination was negative

Radiological examination showed a tumour extending outwards from the mediastinum (Fig 5) The lateral view showed this tumour to be occupying the region of the costo vertebral groove Malignant disease was diagnosed and operation was carried out on November 26th 1931 A portion of the eighth rib was resected and the growth was found in the costo vertebral groove It was attached to the lung and had spread out from it A small portion was excised and fifteen 1·5 millicurie radon seeds were inserted as evenly as possible throughout the growth The chest was sutured The post operative reaction was slight and convalescence uninterrupted

Histological examination of the growth showed that the tumour was a squamous celled carcinoma Further x rays showed the growth to have largely disappeared (Fig 6) Pain has now completely gone and the general condition of the patient is improved while there has been a gain in weight

OTHER MALIGNANT CONDITIONS

Endothelioma appears to arise as a more peripheral growth and it has been possible on two occasions completely to extirpate the growth by removing the lower lobe One of these cases is still living and well three years after operation

Sarcoma is more rare in the lung itself Only one case has been encountered and in this the sarcoma was ossified It was removed but the patient unfortunately succumbed from pneumonia in the opposite lung nine days later

Secondary malignant disease will rarely justify operation as in the majority of cases the secondary deposits in the lung are multiple and bilateral However one patient in whom a partial pneumectomy was performed for a secondary deposit has survived for four and a half years without further symptoms

CONCLUSIONS

Modern methods of investigation enable a much earlier and more correct diagnosis of intrathoracic growths to be made and often assist one to determine the exact nature of these tumours These methods entail

1 Careful radiological examination of the chest from the antero posterior lateral and oblique aspects

2 Further radiological examination after the induction of artificial pneumothorax or gas replacement of effusions

3 The delineation where indicated of the bronchial tree by lipiodol

4 The introduction of the thoracoscope into a pneumothorax cavity where this is possible for visual examination of the superficial surface of the lung and pleura and determination of the superficial characters of the tumour —projection into the pleura

5 Bronchoscopic examination where lipiodol gives evidence of bronchial obstruction or in cases where haemoptysis is a prominent feature and in which the sputum is negative for tubercle bacilli after several examinations

In spite of these methods exact diagnosis will be impossible in certain cases and it is in these that exploratory thoracotomy should be advised with certain precautions

The operation is of no greater severity than exploratory laparotomy and in fact the convalescence is often shorter By this means tumours which were apparently malignant have been proved to be benign and have been successfully removed, while others definitely malignant have been found operable

The hope of satisfactory treatment of all types of intrathoracic new growths benign or malignant depends upon early diagnosis

A CASE OF PORENCEPHALIC IMBECILITY

BY

RICHARD J A BERRY, M D, F R C S, F R S E
DIRECTOR OF MEDICAL SERVICES

AND

R M BATES I R C S Eng
RESIDENT MEDICAL OFFICER
STOKE PARK COLONY STAPLETON BRISTOL

(With Special Plate)

There recently died in Stoke Park Colony an adult female imbecile whose case presents some interesting features apart from the developmental errors revealed in the nervous system at the post mortem examination

CASE RECORD

R B born in or about the year 1905—exact date unknown—was admitted to this institution on October 26th 1920 She was certified as a microcephalic feeble minded patient of low mentality unable to settle down for any length of time to any occupation and not to be depended upon to do any work properly The certifying medical man returned her physical condition as normal and as she was a guardians case of apparently unknown parentage was unable to furnish any family or social history The then medical officers of this institution regarded her as a retrograde imbecile quiet well behaved dull apathetic without any interests The matron in charge stated that she was small for her age of pale unhealthy complexion with no signs of wasting or paralysis of any of the limbs and with no deafness or dimness of vision She was stated to be lively at times with occasional attacks of bad temper She had practically no educational attainments and was only able to do a little simple sewing under supervision

The patient's health remained generally good until January 27th 1930 when during drill in the afternoon and coincident with a menstrual period she was suddenly taken ill and had a bit of twitching and jerking of the face and arms She was put to bed whereupon she had a second attack with loss of consciousness On examination the same night she was found to have a flaccid paralysis of the right arm and leg The next day while still unconscious the patient was removed to hospital and apparently recovered consciousness the day after admission The notes state that six days after admission she was restless excited and sometimes incontinent but was now able to move her right leg though not her right arm The urine was loaded with albumin and continued so throughout the illness The patient was treated in hospital for chronic nephritis until April 1931 but as she had been walking with a special boot since January 1931 she was then returned to the care of her own house matron but remained under regular medical observation

In September 1931—that is about twenty months after her seizure—she came under the care of the present medical staff of the institution She was then found to be suffering from advanced renal disease with a systolic blood pressure of 150 and signs of renal failure She was therefore readmitted to hospital The old right hemiplegia was still apparent and there had been very little improvement in the upper limb She complained of dimness of vision in the right eye and examination of the fundi showed that the optic disks were pale and the retinal blood vessels greatly engorged The urinary output was diminished in amount and in December the patient had three uraemic convulsions The general condition became steadily worse subcutaneous and submucous haemorrhages appeared in the beginning of January and the patient died on January 21st in uraemic coma Clinically therefore the case appeared to be one of imbecility complicated by chronic nephritis Post mortem macroscopic examination seemed to confirm this as the kidneys were reduced to half their normal size and showed advanced chronic nephritis There was also fibrinous pericarditis and what appeared to be the remains of an old cerebral haemorrhage over the lower half of the central sulcus in or about the Sylvian fissure as well as a cyst like structure on the left cerebral hemisphere in the vicinity of the parieto occipital fissure Subsequent examination showed however that the

cerebral appearances were misleading, as they were due to porencephaly, the result of a partial developmental failure and not to any gross visible haemorrhage.

COMMENTARY

Anatomical Considerations

At a very early stage of embryonic life the wall of the neural tube from which the brain and spinal cord are developed consists of a single layer of columnar cells which quickly become multilayered. In this latter form the now thickened wall of the neural tube consists from without inwards of the following:

(*a*) An external limiting membrane.
(*b*) A middle syncytium
  1. Marginal layer (white matter)
  2. Mantle layer (grey matter)
  3. Ependymal layer (ventricular wall)
(*c*) An internal limiting membrane.

In certain parts of the telencephalon (cerebral hemispheres) and possibly also of the metencephalon (cerebellum) the middle syncytial layer has in this case remained permanently in its embryonic state and no brain cells have been developed therefrom. Developmentally the telencephalon consists of three regional parts—the corpus striatum, the rhinencephalon or archipallium (olfactory brain) and the neopallium or true brain. The last two together form the whole of the externally visible hemispheres and are collectively termed the pallium. Just as in any other part of the neural tube the walls of the pallium are differentiated embryologically into ependymal, mantle and marginal layers. The surface extent of the cerebral wall—that is the thin grey cortex (pallial mantle layer)—increases more rapidly than the white medullary layer (pallial marginal layer) which underlies it. As a result the originally smooth pallial wall becomes fissured and convoluted—a device of Nature to increase the area of the neurone bearing cortical strata within a confined space. That portion of the pallial wall which overlies the corpus striatum expands more slowly than the surrounding areas so that the adjacent portions of cortex termed in the adult the frontal, parietal and temporal opercula come to overhang and eventually to conceal the insula or island of Reil and by their apposition to form the lateral fissure of Sylvius. The formation of the opercula commences about the third or fourth month of intrauterine life and shortly after birth these opercula should finally have closed in over the insula. In the brain of this imbecile patient this cortical opercular formation has not taken place at all with the result that there is no insula, no true lateral fissure of Sylvius and no true opercula. Along an oblique line in the primitive pallial wall coincident with the position of the future adult lateral fissure of Sylvius the mantle layer has completely failed to form any cortical grey or white matter whatsoever. At the parieto-occipital end of this oblique line the developmental failure is even more complete, for there is no trace of either marginal or mantle layers with the result that the wall of the lateral ventricle is plainly visible upon and forms part of the cortical surface upon which it appears as a cyst-like structure filled with cerebrospinal fluid. At the frontal end of the same oblique line microscopical examination shows that the syncytial embryonic tissue between the external and internal limiting membranes has persisted and it is this tissue which has simulated the appearances of an old haemorrhage—a natural assumption in view of the history of the case. A similar developmental failure occurred in the right cerebral hemisphere though to a much lesser degree.

Defects of Neurons

On both cerebral hemispheres there are other features of neurological interest such as a diminution in size of many convolutions and cortical areas, imperfection of cerebral fissuring, retention—on the surface—of unnecessary grey, complete absence of certain parts of the cerebral hemispheres and a gross diminution in the size of the corpus callosum, centrum ovale, projection and association fibres and areas and of other macroscopic collections of white matter. The inferior surfaces of both cerebellar hemispheres also show an absence of cerebellar grey cortex in areas coincident with Bolk's leg areas and this is most marked upon the right side.

The relatively large areas of totally undeveloped grey cerebral cortex sufficiently explain the patient's imbecility and prove the association of mental deficiency with lack of cortical neurons. That this patient was devoid of such a sufficiency of neurons is shown by the cortical absence just referred to, by the striking reduction in thickness of the corpus callosum which it will be remembered is entirely composed of the medullated axons of cortical cells but in this case was no thicker than a stout piece of cardboard, by the almost complete absence especially on the left side of the centrum ovale which again is normally composed of projection and other medullated axons which have their cell bodies in the grey cortex and by the reduction of both grey and white matter to a thin sheet spread out over the wall of the lateral ventricle. The reduction in grey cortical matter is in this brain so pronounced that it can safely be asserted that von Economo's estimate of 14 000 million neurons must have been reduced by about a third and the imbecility was thus due to this neuronic reduction and to nothing else. This patient was originally returned by the certifying medical man as macrocephalic whereas she was really strikingly microcephalic. Overall head length was 176 mm., overall head breadth 140 mm. and head height 120 mm. which gives a brain capacity of 1 188 c.cm. and a percentile placement of minus 1 representing a very high degree of microcephaly. As measured after death the fronto-occipital length of the cerebral hemispheres was 155 mm. and the greatest breadth 122 mm. The microcephaly is in this case a useful clinical suggestion of a paucity of cerebral neurons.

Interpretation of Hemiplegia and other Defects

Whilst the striking developmental failure of this brain fully explains the patient's imbecility it does not explain the hemiplegia. The clinical history is suggestive of a haemorrhage and at the post-mortem examination the syncytial tissue already described was sufficiently like a blood clot as to be at first mistaken for one. That this was not however the cause of the paralysis is certain and for two reasons: first microscopical examination showed that the supposed blood clot was composed almost entirely of embryonic material and secondly the syncytium was not over the Rolandic motor area but altogether below it so that even if there had been a haemorrhage it could not have produced a hemiplegia. Microscopic cross-section of the left internal capsule too has so far failed to reveal any sign of haemorrhage so that pending more careful microscopical examination it is as yet impossible to adduce any satisfactory evidence of the site or cause of the paralysis producing lesion. The possibility of an embolus has not of course been overlooked nor the fact that the patient was menstruating at the time of the seizure but our examination has so far revealed neither haemorrhage nor embolus and there remains the further but unsolved problem of paralysis from a localized cortical uraemic poisoning intensified in the latter years of his life.

As regard the statement that prior to the seizure the patient suffered from nystagmus, deafness, diplopia of vision, examination of the corpora bigemina cortical areas hardly supports the statement. The visual areas are considerably diminished in extent especially of the left side and it is significant that after the seizure she com-

plained of dimness of vision in the right eye. The fact that the patient displayed no marked locomotor disability prior to her attack and showed no signs of wasting or paralysis of her limbs renders examination of the pre-central convolutions of some interest especially on the left side. A comparison in Figs. 1 and 2 on Plate of the areas on the immediate frontal side of the central sulcus reveals the fact that on the right side the area in question appears fairly normal whereas on the left side consequent on the failure of development of the frontal operculum the pre-central convolution appears as though it had been cut in two and the lower half removed. This clearly could not have been the case. It is therefore more probable that the pre-central convolution on the left side has been well developed but that its lower half has been bent forward. This deduction from the observed facts is also supported by the clinical evidence of the patient's ability to spell though her vocabulary was both limited and obscene.

Hints as to Aetiology

An examination of this brain shows that there has been a complete cessation of brain development in one part of the telencephalic wall and that this cessation occurred at about the sixth week of intrauterine life. The result is that the primitive wall of the telencephalic neural tube has been left upon the surface of the cerebral hemisphere along the line of the adult lateral fissure of Sylvius and this failure has been more complete on the left side than on the right. At the sixth week of normal development in about a 10 mm. embryo the five brain vesicles are present and the ependymal mantle and marginal layers of the walls of the vesicles and neural tube are well represented while the aortic arches and cardinal veins are completed. The primitive vessels extend into the head and extremities. On the left side cerebral development has in one part of the telencephalic vesicle ceased at this time. On the right side the developmental failure has been as stated less complete and has occurred much later.

Notwithstanding the extraordinary amount of research on experimental embryology and artificial teratology it does not seem yet possible to give any adequate explanation of the *causes* of these errors and failures of embryological development. In a recent number of the *Journal*[1] Keith stated that lions born and bred in the London Zoo were peculiarly liable to cleft palate but that with an altered maternal dietary during pregnancy a plentiful supply of vitamins and better surroundings this developmental error practically disappeared from the offspring. Are some at least of these developmental failures during pregnancy the result of faulty maternal feeding of an aberrant blood supply or of another allied cause? Or have we to look still further back to a deficiency of the chromatin substance of the parental chromosomes or to the genes 'which determine the course of development of the fertilized egg' for our explanation as to why some embryos manifest these and many other similar, developmental failures whilst others proceed along perfectly normal lines. If the chromosomes are responsible then the hereditary factor once more emerges as a potent cause of amentia. In this case unfortunately nothing is known of either the parentage or the hereditary history but as the patient was a board of guardians case it is probably safe to assume that her ancestry was of that inferior stock from which so many mental defectives seem to spring.

DESCRIPTION OF FIGURES

Fig. 2 shows the left cerebral hemisphere after removal of the meninges. The embryonic walls of the lateral ventricle are clearly visible upon the surface that of the occipital end being devoid of all covering of embryonic tissue whilst the larger and more frontal one is partially covered by such tissue which is the remains of the mantle and marginal layers of the telencephalic vesicular wall. The superior temporal convolutions appear well developed. A comparison of this figure with Fig. 1 which represents the corresponding surface of the right cerebral hemisphere shows the striking difference between the two hemispheres.

Fig. 3 shows the inferior surface of the cerebellum with a large non-cortical area on the right cerebellar hemisphere roughly coincident with Bolk's lobe area and an oblique depressed non-cortical area on the left cerebellar hemisphere. As the chief developmental failure affects the left cerebral hemisphere (heterolateral) and the right cerebellar hemisphere (homolateral) it is difficult to believe that prior to her seizure this patient displayed no weakness of her limbs. The cause of this patient's failure of cerebellar development has not yet been determined but it appears to have been of different origin from that affecting the cerebral.

Fig. 4 shows the internal or medial surface of the left cerebral hemisphere upon which are to be noticed the diminution in thickness of the corpus callosum especially in its occipital half the detachment of the fornix from the corpus callosum the absence of the interventricular foramen of Monro the wide opening of the left lateral ventricle here filled with cotton wool the imperfection of the visual area within and about the calcarine sulcus and the imperfect fissuring of the cortex. The whole of the cortex and white matter of this left cerebral hemisphere is as a matter of fact little more than a thin shell spread out over the wall of the lateral ventricle.

Fig. 5 is a diagrammatic cross-section of the telencephalic vesicle of a 10 mm. embryo (six weeks old) the original walls

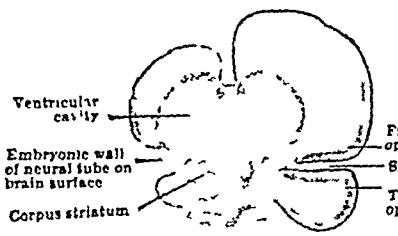

FIG. 5.—Diagram of normal and arrested brain development.

of which are bounded by dotted lines. On the right side there is indicated normal cortical development with a formation of the operculum insula and lateral fissure of Sylvius *whilst* on the left side there is diagrammatically indicated the developmental failure which has resulted in the rather remarkable and instructive brain of this imbecile woman.

CONCLUSIONS

Wigglesworth described in 1897 two cases of porencephaly - and pointed out that it is incorrect to use the term porencephaly as connoting a separate pathological entity since different cases undoubtedly have their origin in different pathological processes. His first case Wigglesworth regards as a true developmental defect. His second case is he thinks not one of developmental defect but has been caused by a definite destructive process of some sort. He inclines to the view that the definite destructive process was an encephalitis the result of injury inflicted during the process of birth not improbably by means of the forceps. He also furnishes a brief list of references to previously published cases. In 1904 Turnbull[2] described a case similar to the present one. He states: 'The cysts seen in the post-mortem examination formed the walls of the posterior portion of the right and left ventricles and represented enormously attenuated portions of cortex.' He concludes that 'the abnormalities consist in a distension of the ventricles and destruction of a large area of the cortex.'

Read in the light of modern embryological knowledge some thirty years later it seems much more probable that all three cases as well as the present one are not due to destruction of previously existing cerebral cortex but to the fact that, developmentally, it was never there. Certainly in the present case the porencephalic condition is the result of an arrest of cortical development in the telencephalic neural wall occurring at or about the sixth week of intrauterine life.

SPONTANEOUS HYPOGLYCAEMIA

BY

ALBERT RAMSBOTTOM M.C. M.D. LRCP

PROFESSOR OF CLINICAL MEDICINE MANCHESTER UNIVERSITY HONORARY PHYSICIAN ROYAL INFIRMARY

AND

CYRIL G. EASTWOOD B.Sc. M.B. CH.B. LRCP. MRCS.

LATE HOUSE PHYSICIAN CLINICAL INSTITUTE ROYAL INFIRMARY

(From the Department of Clinical Investigation and Research University of Manchester and Royal Infirmary.)

(With Special Plate)

The occurrence of spontaneous hypoglycaemia has been noted in the literature several times and it is probable that mild degrees of the condition occur more frequently than is usually supposed. It therefore appears of interest to report the following case.

HISTORY OF THE CASE

The patient, an unmarried children's nurse, aged 44 years, was admitted to the Manchester Royal Infirmary on February 24th 1931, complaining of recurring attacks of dizziness and loss of consciousness.

For some years before 1923 she had been employed as a children's nurse in a doctor's family. In that year however there was a marked alteration in her general behaviour and temperament. She became alternately sulky and self-assertive, often attempting to treat her employers like children (these facts were confirmed by her employer, Dr. Brunwin of Lancaster).

In 1925, having moved to another district, her diet consisted largely of tinned meats with very little carbohydrate. From that time onwards she began to complain of attacks of faintness and trembling, but did not lose consciousness. These symptoms persisted till 1927, when she began to experience momentary losses of consciousness in which she would fall down. Between these attacks she suffered from continual tiredness.

In 1928 the symptoms again altered. There were no more losses of consciousness, but she was often assailed by confusion of ideas while out in the street, and on recovery would, to her surprise, find herself walking in an entirely different neighbourhood from that in which the attack began.

In 1929 the attacks of loss of consciousness returned, recurring every day and followed by severe headache. About this time it was noted that her knee jerks were absent, and that the pupils were unequal and exhibited the Argyll Robertson phenomenon.

In September 1930 she was admitted as an in-patient to the Bradford Royal Infirmary as a possible case of tabes dorsalis. The Wassermann reaction and colloidal gold curve were however found to be negative. During her stay in this hospital she began to lose consciousness almost every day in the early morning at the same time, becoming pale with profuse sweating and a very weak pulse. These symptoms suggested to Dr. Eurich, under whose care he was, the possibility of hypoglycaemia. Accordingly the blood sugar was estimated and found to be 0.046 per cent. Glucose (up to 1.2 lb. daily) was given and her symptoms improved. She was discharged from hospital with the blood sugar at 0.064 per cent. The symptoms of dizziness and twitching returned after a few weeks, and she was admitted to Manchester Royal Infirmary on February 24th 1931. On admission she seemed physically normal, but her manner suggested a neurotic temperament. Inquiry into her family history elicited no hint of importance.

CLINICAL EXAMINATION

General Condition.—Well nourished. On the face and hands a red papular eruption. Tongue, teeth, tonsils, no abnormality. Weight 7 st. 3 lb. 5 oz.

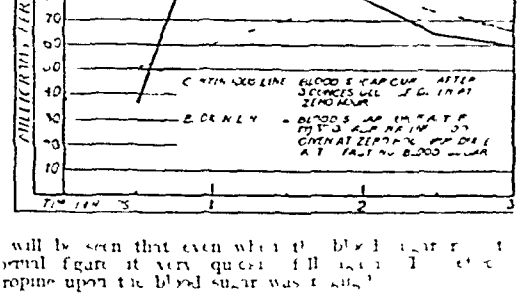
Heart.—No evidence of enlargement. Mitral pre-systolic murmur and reduplicated second sound; accentuated aortic second sound; accentuated pulmonary second sound. Blood pressure 115/75.

Lungs.—Slight dullness and increased vocal resonance medial to the inferior angle of the right scapula.

Abdomen.—Tenderness in right iliac fossa and lower third of course of transverse colon.

Central Nervous System.—Pupils miotic, irregular, and of Argyll Robertson type. Lateral nystagmus both sides. Fundi normal. Cranial nerves normal. Tendon jerks absent. Plantar response extensor on both sides. Sensation normal. Muscular power normal. Sphincters normal.

SPECIAL INVESTIGATIONS



Blood Count.—Erythrocytes 5,030,000 per c.mm. Haemoglobin 84 per cent. Colour index 0.84. Leucocytes 12,200 per c.mm.—polymorphs 77 per cent. lymphocytes 17.3 per cent. large mononuclears 4 per cent. eosinophils 1.7 per cent. basophils nil. Platelets abundant. Nucleated red cells nil. Slight anisocytosis. Occasional poikilocytosis. Wassermann reaction negative. Cerebro-spinal fluid: total protein 30 mg. per 100 c.cm. globulin no increase, glucose 25 mg. per 100 c.cm. chlorides 705 mg. per 100 c.cm. The fluid was slightly opalescent, mobile under normal pressure and gave rise to no coagulum. There were two lymphocytes per c.mm. In addition there were a number of granular bodies which resembled degenerated cells.

X-ray Examination.—No intracranial abnormality; pituitary fossa normal. No abnormality or displacement of gastro-intestinal tract. Basal metabolism increased by 23 per cent. Stools: total fat 24.3 per cent., unsoaped fat 7.7 per cent., combined fatty acids 16.6 per cent. Glucose nil. Urine: lactic acid nil; diastase figure 10. Blood sugar periodic blood sugar estimations were made (see table). The highest

Date	Drugs	Diet	Blood Sugar Per cent.
March 3rd	—	Fluids only	0.031
March 4th	—	Fluid only	0.073
March 7th	G	Minced meat, potatoes, and milk pudding, etc.	0.091
March 10th	GP		0.09
March 21st	A		0.073
April 1st	GA		0.039

G = During period of administration of glucose.
P = During period of administration of protein.
A = During period of administration of adrenaline.

reading was 0.089 per cent., and most of the readings were considerably below this. A sugar tolerance test was performed and a series of estimations were made following the administration of adrenaline (see graph). From these figures

it will be seen that even when the blood sugar was at a normal figure it very quickly fell again. The effect of adrenaline upon the blood sugar was striking.

PROGRESS

On March 1st (five days after admission) the patient became comatose. She was grinding her teeth and sweating profusely. The limbs were flaccid but might be moved, there were no reflexes. She could not be roused to answer questions, and she became incontinent of urine

and faeces She remained comatose for five days when she received 5 minims of 1 in 1 000 adrenaline She then partly regained consciousness and for a short time could be roused to answer questions On the same day she received 10 c cm of 20 per cent glucose intravenously This did not have any observable effect

On March 7th she received 100 c cm of 20 per cent glucose intravenously and the coma rapidly became less profound until she was practically normal

On March 8th she *began to receive 1 lb* of glucose daily by mouth and marked improvement resulted She became *fully conscious of all* that went on but lay in bed more or less mortly with an expressionless face She spoke only in direct answer to questions, with a slow monotonous drawl She received glucose *in this way* throughout her stay in hospital At one time she also received a small dose of pituitrin twice daily and at another period adrenaline twice daily Neither of these drugs produced any effect

On April 16th she began to have *epileptiform* attacks These occurred mostly during the night and alternated with attacks of hysteria which were always controlled by the administration of glucose

On April 22nd laparotomy was performed by Mr Charles Roberts There was no evidence of pancreatic abnormality but the gall bladder contained stones and the appendix was distended by mucus to a size 6 by 1½ inches (see Plate) Cholecystectomy and appendicectomy were performed After operation her condition improved for about a week when the hysterical attacks returned

On June 10th she was transferred to the convalescent hospital at Cheadle on a daily dose of *1 lb of glucose* While there her condition remained the same

Discussion

In this rather complicated clinical picture the low blood sugar is the most striking fact How far the other symptoms can be attributed to this is not quite clear There is no doubt that the administration of glucose improved the condition and as shown by the sugar tolerance test raised the blood sugar for a time Nevertheless, although glucose prevented coma the patient continued to have attacks of apparent hysteria even while receiving 1 lb of glucose daily

A certain amount of experimental work has been done on this subject [1] [2] [3] [4] [5] [6] *and from the results we can form some idea of how far the symptoms in the present case* depended upon the low blood sugar content It has been shown[1] [3] that when hypoglycaemia is induced in normal individuals a symptom complex occurs similar to the present case Experiments upon animals give rise to the same type of symptoms, and in animals at all events *the condition* appears to be hereditary [4] Severinghaus and his co-workers[5] produced hypoglycaemia by injection of insulin into normal people and found that *the blood sugar* was lowered by various amounts down to 0 05 per cent This gave rise to slight incoordination and confusion of ideas resembling those described in the earlier stages of the present case This would suggest that the condition was progressive and gradually became more severe up to the time when the patient came under our care Sendrail and Planques[6] cite eight authorities who agree that any reading below 0 09 per cent constitutes hypoglycaemia *so that* between this and the readings in the present case there are likely to be symptoms of all degrees of severity Milder cases, in which attacks of coma have not occurred respond to a more liberal diet with frequent meals [7] More severe cases require the administration of large amounts of glucose [8] [9]

Causes of Hypoglycaemia

These have been set forth at length by some writers [10] [11] [12] and they fall into five groups (*a*) pancreatic (*b*) endocrine (*c*) hepatic (*d*) renal (*e*) nervous

Pancreatic Causes

Any factor which leads to an over production of insulin may be expected to bring about hypoglycaemia Pancreatic tumours may do this and a number of such cases have been reported [13] [14] [15] [16] The tumours have been either simple adenomas or carcinomas In one case[13] there was a primary carcinoma with secondaries in the liver and from these insulin was recovered *In contrast to this is* a case[16] in which the patient showed the symptoms of *hypoglycaemia* and at necropsy tumours were found in the liver but no insulin could be recovered from them Six cases[17] [18] were discovered at operation and the *tumours were removed, with complete relief of symptoms* Another case[19] showed no tumour but hypertrophy of the islets This again indicates an over production of insulin as the cause of the symptoms The reverse condition was found in a case reported by Pemberton [2] in which the patient had shown symptoms similar to those we have described but post mortem examination revealed a fibrotic pancreas devoid of islets It is not obvious how this could have given rise to *hypoglycaemia*—hyperglycaemia would have been more understandable Cases have been noted [1] in which hypoglycaemia occurred with a normal pancreas and the symptoms were relieved by resection of part of the normal organ From this it would appear that a normal pancreas may be overactive or else the cause of hypoglycaemia in these cases was non pancreatic

Endocrine Causes

Decreased blood sugar is known to be associated with hyperthyroidism and with pituitary dysfunction In the present case there was no obvious goitre but the basal metabolic rate was increased by 23 per cent This may indicate some hyperthyroidism but not sufficient to account for the very severe symptoms We found *nothing* to indicate pituitary dysfunction and a ray examination revealed no gross change in the region of the pituitary fossa

Hepatic and Renal Causes

We were not able to investigate the hepatic and renal functions as carefully as we should have liked Absence of sugar *in the urine* indicates that the condition was not due to a lowered renal threshold

Nervous Causes

The signs in the eyes suggested the possibility of increased vagal action as a cause for the hypoglycaemia However the administration of atropine although it was repeated on several occasions, had no effect upon the blood sugar

Conclusions

Cases of hypoglycaemia associated with widely different pathological states are recorded The majority appear to be connected with progressive lesions of the pancreas In our case, however so far as could be seen from a naked eye examination of the pancreas no demonstrable lesion was present The only pathological conditions discovered were gall stones and a greatly distended appendix and the prominent physical signs—namely *Argyll Robertson pupils extensor plantar* response, and irregular pupils—suggested a lesion of the central nervous system Therefore it has occurred *to us that the* dysfunction of the pancreas leading to hyperinsulinism may be a reflex phenomenon secondary to an infected gall bladder and *in view* of the fact that temporary insulinism produces absence of reflexes with extensor plantar responses persistent insulinism may produce this condition permanently—also dysarthria and Argyll Robertson pupils—by acting on the bulb and mid brain

COMPRESSION FRACTURE WITH COMMINUTION OF BODY OF THIRD LUMBAR VERTEBRA AND NEURAL ARCH OF FOURTH VERTEBRA WITH PARAPLEGIA

BY

H DAVID ISAACS MD LRCS

RESIDENT SURGICAL OFFICER QUEEN MARY'S HOSPITAL, STAFFORD

(*With Special Plate*)

Watson Jones (*British Medical Journal* February 21st 1931) published for the first time a safe and simple method of treating crush fractures of the spine Hitherto these cases had been looked upon apathetically and the results of the usual simple recumbency method of treatment had inevitably been followed by serious deformity and crippling Davis of Erie (Pa) had devised a method where traction and forcible hyperextension were combined with suspension of the anæsthetized patient by the heels from the roof of the operating theatre and Hershkoff described a case of reduction in which four strong men had combined to exert traction on the patient's spine

Aetiology of Crush Fracture

The mechanism in crush fracture of the vertebral body is indirect injury—that is a bending or hyperflexion of the spine associated in some cases with compression in the long axis of the column Falls on the back of the head from a height or a heavy weight falling on the back while it is in a stooping position are examples of this

When the spine is forcibly flexed the first effect is a compression of the bodies of the vertebræ and of the intervertebral discs The upper vertebræ tend to be displaced forwards but are held behind by the articular processes which prevent any further movement Should the flexion continue the lower articular processes of the upper vertebra ride up and jump the upper processes of the vertebra below and a dislocation takes place Compression fracture of the vertebral body without displacement is met with in the dorsal and lumbar regions particularly the twelfth dorsal and the first lumbar vertebræ and also in the upper part of the dorsal vertebræ in the region of the fourth The latter is frequently associated with a fracture of the sternum opposite these vertebræ The cause is always an indirect injury compressing the vertebral column in a vertical direction and causing hyperflexion The soft spongy bone is compressed between the upper and lower laminæ of compact bone Owing to the presence of the pedicles behind the posterior part is strengthened the crushing being more marked in front than behind The result may be a complete comminution of the soft cancellous bone which may be broken up into innumerable fragments and displaced in all directions—usually forwards as this is the direction of the violence

Anatomical Considerations

The anterior common ligament is a strong band of fibres which extends along the anterior surfaces of the bodies of the vertebræ It is broader below than above thicker and narrower in the thoracic than in the cervical and lumbar regions being somewhat thicker and narrower opposite the bodies of the vertebræ than opposite the intervertebral fibro cartilages It consists of dense longitudinal fibres which are intimately adherent to the intervertebral fibro cartilages and the prominent margins of the vertebræ but not to the middle parts of the vertebral bodies In the latter situation the ligament is thick and fills up the concavities on the anterior surfaces and makes the front of the vertebral column more even It is composed of several layers of fibres of which the most superficial are the longest and extend between four or five vertebræ The intermediate fibres extend between two or three vertebræ and the deepest reach from one vertebra to the next At the sides of the bodies the ligament consists of a few short fibres which connect adjacent vertebræ (Gray) Reduction depends on the integrity of this anterior common ligament The process of hyperextension puts this ligament into tension which in its turn presses the fragments back into position and so moulds the vertebræ back into form Thus pressure on the cord by the laminæ of the intact vertebræ above is immediately released and unless irrevocable damage such as crushing or severance is effected recovery takes place

CASE RECORD

This is well illustrated by the following case

J D aged 50 was admitted to Queen Mary's Hospital on August 11th 1931 having been knocked down by a lorry He did not lose consciousness and remembers being crushed between the front axle of the lorry and the ground—that is his shoulder being under the front axle his trunk in a position of hyperflexion

On admission he was suffering from shock and complained of pain in the small of his back inability to move his legs and also that he could not feel them He was immediately turned over on his face and nursed in that position until two days later when reduction was effected

On examination the spines of the dorsal and upper lumbar region were normal until the mid lumbar region when a depression was felt the spine above forming a projection with a depression for two spines level below this X rays taken in lateral and antero posterior position showed marked comminution of the body of the third lumbar vertebra with forward displacement of the greater part of the body into the abdominal cavity and fracture of the neural arch of the fourth (Fig 1 on Plate)

Examination of the spinal cord revealed a complete flaccid paraplegia with complete anæsthesia or paralysis of all reflexes below the level of the lesion Left leg flaccid complete paralysis having an effort to contract the quadriceps extensor muscle sensation to touch and sense of position completely abolished The patient was unable to void urine and evacuate the bowels Catheter specimens were performed

Progress

August 12th 1931.—Patient was given morphine 1/4 grain and laid face downwards his arms resting on a high window ledge the lower part of the thighs on an operating table which was lowered to its extreme limit his body being curved and with the shoulders about 2 feet higher than the knees He had to be supported by two porters one each side holding a shoulder Plaster of Paris was applied from the shoulder to the greater trochanter An x ray taken next day showed the result—complete reduction of the fracture (Fig 2) *Immediately the plaster jacket was applied* he was very comfortable and in no pain Next day there was some return of power in the left leg and he could contract some groups of muscles and he complained of tingling in his legs The bowels were costive and an enema aided by pituitrin was necessary to secure an evacuation

During the next few days *motor power and sensation* gradually returned particularly on the right side reflexes on both sides being however still absent Urine was drawn off twice daily by catheters under strict aseptic precautions

August 26th 1931 (fifteen days after the accident).—The patient passed 12 ounces of urine normally but he had to be catheterized until September 13th since which time he has been able to void in the usual manner *Motor power* and sensation and reflexes returned gradually By August 21th there was complete recovery

October 10th.—He was allowed up and out of bed

October 16th.—Able to walk unaided up and down the ward

December 21st.—Plaster removed

February 1st 1932.—Electric reaction of muscles of lower limb showed normal responses and *complete recovery* He could now walk unaided X rays taken later confirmed the reduction The spine was in excellent position and there was no atrophy of body of third lumbar vertebra He would now have been able to resume his work but for polyarticular rheumatism an intercurrent infection

SUMMARY

This case illustrates a simple method of reducing severe comminuted fracture of the spine accompanied by severe cord injury It would have been impossible by any other method to approach replace the fragments and maintain them in *position* He has recovered completely, both as regards his fracture and the cord injury This method provides an easy way of nursing patients changing their position and avoiding the usual complications of bed sores and respiratory troubles

I wish to express my thanks to Mr Percival P Cole F.R.C.S. under whom this case was admitted and by whose kindness I had the opportunity of treating the case and publishing these notes

CHRONIC GASTRIC ULCER IN A BOY AGED 13

BY

MICHAEL OLDFIELD B.M. B.Ch.

(With Special Plate)

Chronic gastric ulcer is rare in children, although acute peptic ulceration both of the stomach and of the duodenum is not uncommon in infants under a year old Acute and chronic ulcers are more common in *adult life* and it would be interesting to know what percentage of patients who come for treatment at a later date have had preceding ulcer dyspepsia in childhood Proctor[1] describes sixteen such cases at the Mayo Clinic

Children are rarely brought up for treatment for dyspepsia of the ulcer type since this is only associated with the chronic disease They are seen more commonly following the dramatic complications of acute ulceration such as melaena haematemesis or perforation Pauss[2] Theile[3] Robinson[4] and Holm record cases of perforated chronic gastric ulcer in children which were operated upon successfully and Proctor[1] Weber[6] and Miller[7] report cases of chronic gastric ulcer in childhood not submitted to operation Among 1,596 cases of gastric ulcer observed in the Mayo Clinic only one occurred in a child Professor Stewart[8] in a series of 200 cases of chronic gastric ulcer coming to post mortem at the General Infirmary at Leeds *found none under 10 years and three* between 10 and 20 years of age Deaths from chronic ulceration are obviously extremely rare in childhood It is possible however that if a careful history were taken an account of a preceding typical dyspepsia in childhood might be obtained in many adult cases of chronic peptic ulcer This would emphasize the importance of giving rigorous and prolonged treatment to children suffering from chronic dyspepsia

CASE REPORT

H. W. a pale thin boy aged *13* was admitted to the General Infirmary at Leeds under the care of Dr Veale on December 4th 1931 for haematemesis

History.—When the patient was 11 years old he had a series of sore throats followed by indigestion This consisted of an aching pain in the epigastrium when he was hungry The pain was so severe that it wakened him during the night It was relieved by food and was occasionally accompanied by vomiting Symptoms were intermittent bouts of pain lasting two to three weeks alternating with periods of freedom The pain gradually grew worse but it was not for over a year after the onset of this symptom that the patient was taken by his mother to the doctor Frequent small milk feeds and alkalis were given and later tonsillectomy was performed The symptoms disappeared within a fortnight

Before breakfast on the morning of December 4th 1931 the boy had a sudden stabbing pain in the epigastrium and mid sternum He became thirsty and then vomited about half a pint of dark red clotted *blood* He was admitted to hospital the same day

Physical Examination.—*His face was pale* his lips and conjunctivae were blanched Pulse 120 Temperature 98.1° *Respirations 24* There was slight epigastric tenderness There was no evidence of bleeding from the nose or mouth The spleen was not palpable *The heart lungs nervous* system optic disks and urine showed nothing of note No septic foci were found in the nose ears or throat

Special Examinations.—(1) Occult blood was present in the faeces (2) A blood count showed mild secondary anaemia (3) A Rehfuss test meal showed a high normal acidity—that is 1¾ hours after the meal the total acids were equivalent to 80 c.cm. *N/10 NaOH* per 100 c.cm. of gastric contents Free hydrochloric acid reached 0.2005 per cent equivalent to 55 c.cm. *N/10 NaOH per 100 c.cm.* of gastric contents There was slight delay in emptying of the stomach complete after 2¾ hours (4) *X ray examination* showed a small ulcer crater on the posterior surface of the stomach close to the lesser curvature three inches from the pylorus

Progress.—The patient was treated medically by prolonged rest in bed starvation followed by Hurst's dieting Olive oil and belladonna were given alternately before meals alkalis after meals He remained in bed in hospital for seven weeks and was free from symptoms when discharged He stayed in bed at home for another five weeks

On March 1st 1932 he came up to hospital A radiograph was taken no ulcer crater was to be seen A Rehfuss test meal showed the gastric ulcer diathesis to be present still There was a high normal acidity—that is in the specimen taken 1¾ hours after the meal the total acids were equivalent to 95 c.cm. *N/10* NaOH per 100 c.cm. of gastric contents Free hydrochloric acid reached 0.219 per cent—that is equivalent to 60 c.cm. *N/10 NaOH per 100 c.cm.* of gastric contents There was still slight delay in emptying of the stomach complete after 2¾ hours Seven weeks have elapsed

since the boy was discharged from hospital so far there has been no return of symptom

I am indebted to Dr R A Veal for permission to publish this case and to Professor M J Stewart for his kind advice

OEDEMA IN THE NEWBORN*

BY

JOHN GIBBONS M B Cantab M R C P Lond

CHIEF ASSISTANT IN CHARGE OF INFANTS QUEEN CHARLOTTE'S AND CHELSEA HOSPITAL FOR WOMEN CHIEF ASSISTANT TO THE CHILDREN'S DEPARTMENT ST THOMAS'S HOSPITAL

Oedematous conditions in the newborn are of fairly common occurrence but experience seems to show that it is difficult for the average man faced with a case of this kind to form a clear idea in his mind of the most likely cause of the disorder and of the appropriate treatment A study of the textbooks does not usually help very much they describe congenital oedema oedema neonatorum sclerooedema sclerema sclero oedema etc but no two authors seem to agree exactly as to the precise definitions

With the idea of simplifying this subject a little I have collected a few cases with oedema as the leading physical sign in which it will be observed that the main aetiological factors are cold and sepsis I am excluding entirely those rare cases in which the baby is born with generalized oedema ascites and hydrothorax or with massive oedema of the limbs and often dies a few hours later In general practice it is very unlikely that such a case will ever be seen in view of the fact that only one example of this condition has been observed at Queen Charlotte's among 12 000 babies born during the last six years

In my experience the commonest cause of oedema in the newborn localized or generalized is cold and in my opinion it is absolutely essential that this should be realized by every general practitioner or nurse in charge of a newborn infant The temperature as taken with the ordinary clinical thermometer (with a low limit of 96°) in the axilla or groin gives quite a false idea of the actual temperature of the infant One must use a subnormal thermometer with a low limit of 88° There is no difficulty in getting these in practice and they are not expensive The temperature must be taken rectally Neglect of these simple precautions leads to much trouble when dealing with newborn infants especially when they are premature or debilitated It is quite common to hear a nurse say that the baby's temperature is perfectly normal somewhere about 96° (the lowest reading on her thermometer) when on putting a hand on the baby's abdomen and legs they feel definitely chilly and the temperature taken rectally with a subnormal thermometer is found to be 93° or even lower The importance of warmth for the newborn infant is I think still not fully appreciated and naturally the more feeble and premature the child the more the necessity for keeping a close watch on the temperature I have seen a child three or four days after birth in a cold house in a bad slum area quite chilly and blue gasping for breath and apparently of rectal temperature—89° On putting the baby into a hot bath for twenty minutes a Lane's coil to be changed every four hours for twenty-four hours has been placed round it there has been prompt recovery

Probably many infants are certified as having died of atelectasis prematurity congenital debility and the like when in reality death is due to the effect of cold

Injurious Cold

The newborn infant then is particularly susceptible to the effects of cold The following cases all of which occurred in this hospital are I think excellent examples of cold acting as a cause of oedema

Case I

Twin boy seen on December 3rd 1931 on the ninth day of life at Queen Charlotte's Auxiliary Hospital Caledonian Road because of swelling of the penis Birth weight 5 lb 6 oz The weight had gone down to 5 lb on the third day of life but by the ninth day it was 5 lb 8 oz The mother was a primipara aged 27 perfectly healthy the delivery was normal the first twin being a L O A the second a I O P This case was the first twin

On the sixth day mild oedema of the prepuce was first noticed and when seen on the ninth day the oedema was very marked no oedema of the scrotum There was no difficulty in micturition and the urine was normal Both testicles were in the inguinal canal There was also considerable oedema of the eyelids and pitting oedema of both feet and shins and of the scalp Heart lungs abdomen and throat were normal Pulse rate 120 Since birth the infant had had a subnormal temperature varying from 93° to 96° No hot bottles had been used but the infant had been kept in a cot near a gas fire The baby's feet and head felt cold and the rectal temperature was taken with a subnormal thermometer and found to be 93°

The baby was put in a hot bath at 105° till the temperature was 99° and hot bottles were put in the cot and the rectal temperature was taken four hourly for the next four days Next day the temperature was 96 8° and there was much less oedema By December 6th 1931 the oedema was completely gone and as was expected with the disappearance of the oedema the weight dropped 4 oz in the three days One month later the baby was completely normal

Final diagnosis Oedema due to hypothermia

Case II

In view of the above case the other twin was examined although supposed to be quite normal Birth weight 5 lb 4 oz Weight on the ninth day 5 lb 4 oz Here also the temperature had always been low varying from 96° to 98° On examination there was pitting oedema of the scalp both feet shins and thighs also slight oedema of the eyelids and prepuce Urine normal Heart lungs abdomen normal The rectal temperature was 93° Similar treatment was adopted and in four days all trace of oedema had vanished the loss of weight in this case over four days was 1/2 lb One month later the baby was perfectly normal in every way

Final diagnosis Oedema due to hypothermia

Oedema may occur (1) if the infant is put into a warm bath immediately after birth without ever having had a subnormal temperature and (2) if the temperature is subnormal In the latter case the oedema is more frequent and more severe Cold therefore is a contributory factor but the main factor is poor development of the circulatory system and the vessels and blood vessels that are delicate and friable Pitting oedema of the feet is due to dependent oedema of gravity this could easily develop in the arms and legs to bring down when there is swelling of the dependent parts such as the face If the foot of the cot is raised for warmth the baby's head is kept lower than the feet the oedema of the feet drains in a few hours and

* Lecture delivered at Queen Charlotte's Hospital

completely vanished in twenty four hours at the same time oedema of the scalp appears This is not true of all cases for occasionally the oedema of the feet lessens, but does not entirely disappear with change of posture As the infant gets older the strength of the circulation improves and by the age of 3 to 4 weeks all trace of oedema has usually vanished No treatment is required for this type of oedema beyond keeping the baby's temperature normal Naturally if the baby is allowed to run a temperature persistently several degrees below normal the oedema will take longer to disappear

SCLEROEDEMA AND SCLEREMA

In infants as in adults the capillaries are extraordinarily susceptible to cold and if the temperature is allowed to remain subnormal for long serous exudation may take place into the skin and subcutaneous tissues and we have the conditions known as scleroedema and sclerema There is no sharp distinction between oedema scleroedema and sclerema and one occasionally sees a case showing characteristics of two of these conditions simultaneously in all probability it is merely a question of degree depending on the water richness of the tissues and the anatomical distribution of the subcutaneous fat The younger the infant the less the fat deposit but even in the smallest premature infant the fat deposit on the external aspect of the thigh is a few millimetres thick while elsewhere fatty tissue is extremely scarce Consequently if oedema of the feet is present the skin and subcutaneous tissues over this part of the thigh always feel rather hard and firm (scleroedematous) in contradistinction to the soft oedema of the genital region and the internal aspect of the thigh and leg If this hard firm feeling becomes well marked we have the condition known as scleroedema In this the skin and subcutaneous tissues are hard and tough and cannot be picked up properly into folds The skin has a peculiar mottled dead appearance Usually the lower limbs especially the outer aspect of the thighs (for the reasons given above) are involved but the condition may extend so widely up the trunk and limbs that all movements, even sucking are difficult The eyelids and the scrotum are never involved The temperature is subnormal usually about 90° to 93° but it may be as low as 86° and even 77° is recorded Related to this are the extreme lack of movement, the superficial breathing the feeble voice and the small slow pulse—in fact not unlike a case of myxoedema The treatment is simple—namely warmth at all costs—hot baths hot bottles, etc—massage to the limbs and of course breast feeding Since these cases so resemble myxoedema thyroid extract has been given with the idea of stimulating the basal metabolism with excellent results Dr Eric Pritchard recommends that ext thyroid sicc (B W & Co) 1/8 to 1/6 grain should be given three or four times a day and with this dosage I have seen good results when treatment is combined with warmth

A clinical picture somewhat different from this is provided by the infant suffering from sclerema a circumscribed symmetrical fat sclerosis Here the temperature is commonly raised and the infant has small plaques in the subcutaneous tissues over which the skin is reddened, these tend to be symmetrical especially on the cheeks buttocks upper arms and thighs They are very like multiple lipomata, but are harder and attached to the skin not to the subcutaneous tissues With massage they usually disappear after a few weeks Histologically necrosis of the fatty tissue with sheafs of fatty acid crystals are found also oedema cellular infiltration and numerous giant cells The cause of the condition is still unknown

OEDEMA FROM SEPSIS

The second factor we have to deal with is sepsis and one may take the following case as a typical example of this

CASE III

Baby John M born at Queen Charlotte's Hospital on June 17th 1931 with a birth weight of 6 lb 8 oz When seen on July 1st there was considerable pitting oedema of the right thigh reaching high up as far as the crest of the ilium also oedema but rather less of the right foot and shin No oedema of the left leg The temperature of both legs seemed equal and the skin was everywhere normal apart from the oedema Full range of movements of both legs normal tongue Rectal examination nothing abnormal found Nothing abnormal found in the heart lungs abdomen, or central nervous system urine normal For the previous week the baby had been mildly jaundiced Breast fed for one week then owing to failure of breast milk the child was given an ordinary modified milk mixture Two weeks before the baby was born the mother had had puffiness of the face and ankles Owing to poverty her diet had been cut down considerably during the last months of pregnancy no fresh milk had been taken but she had apparently taken plenty of oranges lettuces tomatoes etc No oedema of the ankles was present at this time and the urine was normal Hot bottles were ordered to be placed against the baby's right leg

July 2nd—*Oedema of the right leg unchanged but now* considerable pitting oedema of the left leg and oedema extending upwards over the pubis almost to the umbilicus Urine (sterile catheter specimen) acid reaction faint trace of albumin no sugar pus or blood Cultures showed a few colonies of *B coli* Orange juice 1 oz twice daily was ordered cod liver oil 1 teaspoonful daily and plenty of water

July 7th—The oedema of the legs and pubis has gradually become very marked and abdominal distension is now developing No sign of intestinal obstruction no ascites and nothing abdominal felt per rectum Abdomen tense but apparently no enlargement of the liver or spleen Baby taking feeds well no vomiting Temperature varying between 98 6° and 99 8° *Weight curve stationary* for the last eight days at 6 lb 8 oz Normal stools Examination of a sterile catheter specimen of the urine showed no pus cells but Gram negative bacilli were present which proved on culture to be *B coli*

July 8th—Massive brawny swelling developing over the left thigh with two small areas of fluctuation Much less oedema of the left leg and foot and of the right leg Abdomen softer Aspiration of the fluctuating areas 1 c cm of thick yellow stinking pus obtained which showed a pure growth of *B coli* Cod liver oil 1 teaspoonful three times a day and orange juice 2 oz daily were given

July 10th—Massive oedema and infiltration of the subcutaneous tissues of the left thigh still present pus again removed by aspiration

July 14th—No areas of fluctuation but still a lot of infiltration An incision was made down to the bone over the anterior aspect of the femur and a large amount of pus gushed out

July 17th—Thigh still very infiltrated An incision was made over the greater trochanter down to the bone and again pus was found Following this the oedema and infiltration rapidly diminished and the child was discharged well with the abscesses soundly healed on August 19th weighing 8 lb 6 oz and having gained nearly 2 lb in the six weeks of treatment Urine normal

This child was seen at frequent intervals till the age of 6 months and there was never any recurrence

Diagnosis Oedema due to deep *B coli* abscesses of the left thigh

GENERAL CONCLUSIONS

Nephritis as a cause of oedema in the newborn I have never seen and judging from the literature either it is very rare or does not exist although this diagnosis is often made The youngest cases I know of were twins aged 3 months reported by Finkelstein One baby had

intertrigo extensive oedema and the urine of a haemorrhagic nephritis typical glomerulo nephritis being found post mortem The other twin had oedema but the urine was normal there was complete recovery None of my cases quoted above ever had albuminuria and in one child (case not recorded) that died the kidneys were microscopically quite normal Many of the symptoms such as oedema which were attributed a few years ago to failure of renal function are now believed to be extrarenal in origin the oedema—for example in the typical case of lipoid nephrosis (= chronic parenchymatous nephritis)—being due to a generalized disturbance of salt and water metabolism in which the kidney shares equally with every other vascular organ

It is perfectly possible to have severe oedema without any nephritis and severe nephritis without any oedema Pyelitis in the newborn is not accompanied by oedema—at least not in the half dozen cases I have seen—so examination of the urine in oedema of the newborn practically never gives much help

To sum up then oedema is a symptom of fairly common occurrence in the newborn especially in premature and debilitated infants it is often directly due to the effects of cold in the capillaries and to circulatory weakness If the condition is recognized early and treated promptly the outlook is quite favourable whilst in cases that are febrile it is commonly an early manifestation of sepsis Nephritis is only rarely a cause of oedema in the newborn

LOCAL ANALSTHESIA FOR TONSILLECTOMY

BY

J W COSTELLO M D I R C S Ed

[illegible] [illegible] [illegible]

The difficulty recently experienced by a colleague in finding someone willing to remove his tonsils under local anaesthesia prompts this account of a small series of twenty tonsillectomies done wholly under local anaesthesia The cases were adult private and hospital patients the initial reason for local anaesthesia being the patients desire to avoid a general anaesthetic and a later reason the personal preference of the writer for this method The patients were selected only in so far as they were agreeable to the method and appeared to have ordinary powers of self control In all cases careful examination for other foci of infection was made in order to lessen the risks of troublesome haemorrhage

The general technique employed will be found fully described in my work on local anaesthesia and will be briefly dealt with here particular stress being laid on certain modifications adopted to add to the ease of the patient It is certain that the disagreeable anticipations naturally associated with the operation can be reduced in their fulfilment to something definitely less than the discomforts of many a visit to the dentist Pain should be completely absent throughout but the anxiety caused by the position of strange happenings and what must feel like a core of lethal weapons being rammed home in the victims throat—particularly if the jaw is fixed with a gag—may be so great as to place the operation outside the pale of humane therapy The relief of these feelings however depends upon the handling of the case and the extent to which it may be assisted by the patient In this group who when about to be returned to the ward asked anxiously what had gone wrong and complained that he was being sent back with only [illegible] anaesthetic injected In most cases such a state of affairs cannot be expected to obtain in all cases but it may be closely approximated in a great many cases ordinarily subjected to general anaesthetics

TECHNIQUE OF ADMINISTRATION

Preliminary morphine was given only to an unduly fearful minority and the patients co-operation gained by a short explanation of what was to be expected of him The procedure is as follows

1 The fauces are liberally sprayed with 10 per cent cocaine after cautioning the patient against swallowing any of it

2 In five minutes the injection of 0 75 per cent novocain and adrenaline may be commenced A light spinal and long needle are necessary Injections are made into the upper and lower poles and just outside the margin of the anterior and posterior pillars about the centre Enough should be injected to encircle the tonsil with a band of anaemic tissue and to saturate its bed from which it will project rather more than usual if not too adherent or fibrosed The fracial tissues should not be blown into oedematous folds with the solution

3 By the time the second injection is finished the first tonsil will be ready for dissection This is done with the finger or dissector and scissors but requires considerably more gentleness than is at times used in the dissection of tonsils under general anaesthesia In most cases the work is being done in a field which is nearly dry and one can proceed deliberately The smallest adhesions should be snipped instead of torn It is at this stage that the co operation of the patient becomes particularly valuable as by keeping his mouth well open and pharynx relaxed he will give good exposure of the parts with the occasional help of a tongue depressor used only lightly Any form of gag should be avoided as being too uncomfortable for the conscious patient At any stage the partially dissected tonsil may be held with a swab whilst the patient is allowed to relax his jaw and rest indeed these spells may be encouraged if the tonsil be looked on as a piece of raw tissue and an efficient haemostat

4 After the removal of the second tonsil is completed swabs held in the tonsillar fossae for a few minutes suffice to reduce the haemorrhage to a point which just colours the saliva and the patient is able to walk back to the ward or be driven to his home

COMMENTARY

In no case was there enough bleeding to require the use of a suction apparatus to maintain a clear view of the field of operation throughout Some of the cases were practically bloodless The only complaint made in the first hour or so after the operation was the difficulty in swallowing As the effects of the anaesthetic passed off the patient seemed to complain of rather more first-day pain than is found in the case of those receiving a general anaesthetic This however would be explained by the lack of the dulling effect of a general anaesthetic and a certain sense of disappointment following their early cheerfulness In no case was there any troublesome reactionary haemorrhage the total blood loss [illegible] only a fraction of that usually experienced There was no appreciable difference in the convalescence Perhaps the use of some other solution giving a more permanent partial anaemia of the during of the tonsillectomy with some such substance as adrenaline powder would be desirable [illegible] the after pain and leave the [illegible] only pleasant memories of his tonsillectomy

Without entering into any detailed discussion of the virtues of various methods of general and local anaesthesia [illegible] removed from the [illegible] and satisfactory [illegible] with any local anaesthetic [illegible] tonsillectomy [illegible]

was about thirty minutes Other requirements are a large measure of sympathy and confidence between patient and operator and what may not unfairly be described as a certain daintiness of touch on the part of the surgeon An anæsthetic method which demands these last two qualities seems to be no bad training for a surgeon whether junior or senior and the wider development of them might do much to improve the current standards of local anæsthetic administration which seem too often to justify the unfavourable opinions held of them

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

AN UNUSUAL CASE OF SUBPERITONEAL UTERINE FIBROID

(With Special Plate)

In view of the large size of the tumour and the very slight inconvenience which it caused the following case is I think worthy of record

The patient Miss P first consulted me on January 16th complaining of some slight abdominal pain and discomfort On examination she was found to have a large abdominal tumour of pelvic origin more marked on the left side than on the right and reaching to above the umbilicus The tumour was of firm consistence solid and smooth in outline It was freely movable from side to side and occupied the whole of the lower abdomen It was not painful or tender on palpation Vaginal examination made without anæsthesia was indefinite owing to the absence of relaxation of the patient The uterus was not softened the breasts showed no pregnancy signs menstrual history and date a regular and normal flow and duration X ray examination was negative

Operation performed on January 20th revealed an enormous subperitoneal fibroid arising from the fundus of the uterus and attached by a short pedicle The uterus itself contained several other small fibroids—mural and subperitoneal The pedicle was clamped the tumour removed and hysterectomy performed The patient made an uneventful recovery The weight of the tumour was 8 lb the circumference 30 in the length 9 in and the breadth 6½ in Fig 1 (on Plate) illustrates the size of the growth by comparison with the scale measure by its side

I wish to express my thanks to my partner Dr P Kinmont for his assistance with the case

SIDNEY B RADLEY F R C S
Honorary Surgeon Newark Hospital

FOREIGN BODY IN THE COMMON BILE DUCT

Few cases have been reported of a foreign body being found in the common bile duct Oppel[1] reported a case in which a patient had the operation of cholecystectomy and some four months later developed a fatal peritonitis A swab was found in the common bile duct this had apparently migrated from the peritoneum as the bile duct had not been opened at the previous operation Lemierre and Pollet reported a case in which a liver abscess occurred in an insane patient This was due to a swallowed spoon handle which had entered the common bile duct via the ampulla of Vater Fedoroff[3] reported a case in which following an operation for gall stones the wound was drained by a T shaped drainage tube On the seventeenth day when the tube was going to be removed the vertical portion had already been extruded from the wound while the short horizontal part had remained in the duct (which was opened at operation) For two and a half years there were no symptoms but then the patient developed attacks of colic with occasional jaundice After a further two years the patient was operated on again The tube was found in the retro duodenal portion of the common bile duct and had undergone no changes whatsoever during its five years stay Recovery was uneventful In view of the few such cases reported the following may be of interest

REPORT OF CASE

The patient a man aged 65 was admitted to the Derby City Hospital in June 1931 complaining of indigestion vomiting and pain which he located under the right costal margin He also described a lump which he said he could feel there The history extended back for an indefinite period but his symptoms had been more marked for some two or three weeks There was no history of jaundice or colic On examination the patient was well nourished and on the whole in moderately good health On palpation a rounded tender swelling below the liver suggestive of an enlarged gall bladder was clearly felt There was no general enlargement of the liver and the patient was not jaundiced The temperature was normal His symptoms improved but the swelling continued to be palpable Cholecystography showed no shadow in the area of the gall bladder after fourteen or eighteen hours

At operation the gall bladder was found to be distended and contained a mulberry stone of medium size in the cystic duct some smaller stones being present in the gall bladder Palpation of the common bile duct revealed no further stones but a piece of wire was felt to be projecting through the lateral wall of the duct just below the termination of the cystic duct Cholecystectomy was performed the piece of wire removed and the operation completed in the usual way

During his convalescence the patient was questioned about the origin of the wire but was unable to shed any light on the matter At no time could he remember the possibility of having swallowed it accidentally No previous operation had been performed on the patient and presumably the article in question must have been swallowed at some time and have migrated up the common bile duct

The wire was just under one inch in length and was bent in the shape of an I the shorter arm having perforated the wall of the duct it was steel wire approximately 0 001 inch thick and had not been corroded to any great extent

I am indebted to Dr R Strom Olsen for assistance with the translation of the references

GANGRENE AND PERFORATION DUE TO EMBOLISM OF THE INFERIOR MESENTERIC ARTERY

An account of this condition appearing in the *British Medical Journal* of January 30th 1932 prompts me to record a somewhat similar case that came under my notice a few years ago at a time when I was acting as resident clinical assistant in one of the city mental hospitals

Clinical History

The patient a stout man of about 64 years of age enjoyed perfect health until the onset of this fatal illness His first complaint was that his bowels had not moved for some days and Epsom salts had been taken with no result Castor oil was then given by the attendant in charge and the following day though he complained of abdominal discomfort he still passed nothing per rectum Throughout the day the attendant reported nothing further but on doing the evening round of the institution I examined his abdomen and discovered that it was distended and markedly rigid Slight tenderness was experienced on palpation more marked in the right iliac fossa Pain fairly severe and now constant was complained of all over the abdomen especially in the right iliac fossa Temperature 103° pulse rate about 100 The patient was removed to hospital where a further examination was made on the arrival of the surgeon The abdomen was now board like and severe pain was complained of on palpation There was also collapse and a rapid and feeble pulse On opening the abdomen it was evident that peritonitis had been present The intestines especially the colon were adherent to omentum

ritoneum and fat were pink, the gut being practically black. The appendix was found—pink normal and covered with a good mesh of fat—and removed after securing an appendix stump effected. The patient had died about twenty-four hours after the operation.

Post-mortem Examination.

On opening the abdomen the peritoneal cavity was half full of fluid having a strong fecal odour. We followed the intestines throughout their course. The appendix was still in situ and normal to all appearance except that it was firmly adherent retrocecally. For about six to eight inches the colour of the peritoneum and fat attached was a bluish black and gangrenous, the bowel wall itself being as thin as tissue paper for about three or four inches. At one point in it a hole into which an ordinary match head could easily enter was discovered. Obviously the blood supply to this part of the bowel was partially or completely cut off. There was no volvulus or intussusception. The heart and aorta were removed complete. Heart and proximal aorta appeared normal, and the intima of the aorta was perfectly smooth until the level of the third lumbar vertebra was reached, when for about one inch there was some hard, shelly, calcified material. This surrounded the orifice of the inferior mesenteric artery, which was itself much narrowed. A piece of the calcified material was found impacting the vessel just below the point at which the left colic branch is given off.

Commentary.

The feature of this case was the absence of a history warranting the correct diagnosis. Only a few hours prior to the operation was there any suspicion of an acute abdominal condition. Throughout the illness the patient did not vomit, and the only sign suggestive of acute obstruction was the absolute constipation. Blood or mucus was not passed. Another interesting point was the localized atheromatous change in the aorta at the level of the third lumbar vertebra. The intimal change at that site was rightly or wrongly attributed to the fact that the patient always wore a leather belt round his waist instead of braces, thereby increasing the *local tension** in the artery at that level, a factor which seems to be concerned to some extent in the aetiology of atheroma. The Wassermann reaction was negative.

Reports of Societies

NEPHROSTOMY IN THEORY AND PRACTICE

At the meeting of the Section of Urology of the Royal Society of Medicine on April 21st, with Mr. KEITH JOHNSON in the chair, an address was delivered by Dr. HUGH CABOT of the Mayo Clinic, Rochester, U.S.A., entitled "Nephrostomy in theory and practice."

Dr. CABOT said that nephrostomy as an emergency procedure was a very old operation, but the earliest discussion he could find did not date back beyond the eighties of the last century. At that time two important questions attracted attention—namely, the rapid return of function and the effect of drainage through the kidney substance on infection. After a glance at the historical aspect of the subject he considered the application of nephrotomy in three groups of cases: (1) calculus disease, (2) chronic hydronephrosis with or without infection, and (3) chronic infection of the kidney. In calculus disease he said that the operation was described in cases showing marked dilatation of the pelvis and the calyces. He believed that in the uncomplicated case of infection to an unimportant degree. The only cases [illegible] from the standpoint of chronic infection which had been excised. He referred to the [illegible] of a small [illegible] was [illegible] kidney due personal to one [illegible] which [illegible] had been present for a long period. He [illegible] was [illegible] to regard nephrectomy as the only safe operation. He [illegible] advised that operation if they were [illegible] on the other side even though of quite small [illegible] and doing no great damage. He [illegible] had been on account of the number of cases in which a stone bearing kidney on one side having been removed, stone promptly developed in the other kidney which had been free from trouble for many years. A stone bearing kidney on one side might be in some ways a safeguard to the other kidney. It was certain that in some instances the development of stone upon the other side had been extremely rapid. This suggested the possibility that the disturbance of the chemical mechanism whatever it might be was thrown from the kidney which had developed stones on to the kidney which had not the protective mechanism to look after itself. He was therefore becoming less willing to perform a nephrectomy and more desirous of seeing what could be done with an apparently seriously damaged kidney. In the same group came the cases of pyonephrosis without stone in which undoubtedly a hydronephrosis had become infected. It was in this type of case that the problem of determining the function of the kidneys seemed most troublesome. For many years the fact had been recognized that it was not possible to find out with any accuracy the function of a kidney containing a stone, but in a kidney which appeared to have a considerably depressed function this would return to something approximating to normal after removal of the stone. Cases of pyonephrosis, however, were frequently reported as having a completely functionless kidney; this should mean a kidney incapable of function, but that was not so. He had now the records of forty-two cases in which no function other than a moderate exhibition of water could be demonstrated by the methods available, but after drainage and removal of stone—if stone existed—a return of function to something like 50 per cent. of the original capacity was discovered. Therefore even with the very elaborate and delicate means now used one was not entitled to say that a given kidney was incapable of function. He had been continually surprised by the ability of the kidney to take up its work when obstruction had been removed. It was conceivable that the process which normally went on in the kidney whereby only a portion of the glomeruli were in action at any one time might under adverse conditions extend to the whole kidney, so that it might be possible for the kidney to be allowed for a considerable period. If the active glomeruli were reduced from say 20 per cent. to 3 per cent. the kidney might still continue to live and keep its anatomical structure. At any rate the clinical judgement that a kidney was worthless had often to undergo serious reconsideration. He knew of no method likely to be so helpful as nephrotomy in clearing the possible value of a kidney which had been adjudged to be worthless.

Dr. CABOT next discussed the advantages of nephrotomy as compared with pyelotomy. The first [illegible] much greater certainty of continued satisfactory [illegible] more important question was the effect of nephrotomy on function and on infection. His own experience [illegible] led to the conclusion that the working capacity of the kidney would return to the extent of [illegible] removed kidney to [illegible]. The effect on infection was much more difficult to judge. He did not find in the literature of the years [illegible] any great clear proof [illegible] in the process for which [illegible] had been excised. He referred to the [illegible] and [illegible] the [illegible]

chronic infection however was a much more difficult question At the Mayo Clinic there were a number of patients who had had a nephrostomy draining for several years Thus a kidney of some value was preserved—a kidney which had been severely infected at the start, was always moderately infected commonly showed urea splitting organisms but carried on as a useful organ which it was well to preserve in the presence of an injured kidney on the other side In the presence of two bad kidneys one might think it proper to maintain a kidney of that kind unless it could be shown that it was a menace to the remaining kidney but he did not think that evidence would support that view

To sum up he believed that nephrostomy had a larger field than had been customarily allowed If it was applied to a doubtful kidney infected whether stone were present or not there was a likelihood of the kidney being saved when otherwise it would have had to be sacrificed In a number of cases chiefly with cancer in one form or another permanent nephrostomy was not more socially inconvenient than permanent colostomy He remembered well the day when he regarded permanent colostomy as a condition so shocking that *had he* been the patient he would probably have preferred to die Now it was known that patients lived comfortably with a permanent colostomy for many years The same thing was true of nephrostomy If the tube was accurately placed it could be looked after by the patient himself and changed by him after some experience He was inclined to reinforce a suggestion made by Watson in 1910 that in the presence of bilateral calculus disease a permanent nephrostomy on one or both sides might preserve the kidney tissue from further destruction and he proposed with some reservations that it was just barely possible that nephrostomy in the presence of calculus disease might inhibit or entirely put an end to the further development of calculi in that kidney though he admitted that there was not very much evidence as to that At his clinic there were three patients who had lived for three six and fifteen years respectively after a nephrostomy These had had recurrent calculi and after the nephrostomy had been performed the calculi had not recurred A colleague had reported two cases in one of which he had done a nephrostomy four years previously and in the other two years previously for recurrent calculi and the calculi had not since returned Probably the case of longest duration was that originally reported by Watson in 1910 in which there was no evidence that the calculi increased in number (they had not been entirely removed) and the patient lived with good kidney function and apparently without any further development of calculi for twenty five years after the first operation which took place in 1905 a second operation on the other side being performed in 1909

Sir JOHN THOMSON WALKER raised the question of terminology He thought that in this country the terms nephrostomy and nephrotomy were more rigidly employed than in America Nephrostomy was looked upon as a permanent condition and therefore they did not usually qualify it as Dr Cabot had done by the word permanent Nephrotomy even if it meant draining the kidney for a few weeks was regarded as a temporary condition The surgery of the kidney in this country in regard to bilateral stone was conservative but he could not say it had been his experience that the removal of stone from one kidney encouraged the development of stone in the other In fact the opposite had been illustrated If a stone which was septic was left in one kidney later on one was likely to find stone developing in the other

Mr F A G JEANS expressed his thorough agreement with the remark made by Dr Cabot that if he had a bilateral condition of calculus he went for the best kidney first

Mr JOCELYN SWAN said that he was a little bit sceptical as to whether the improvement in renal function after drainage as recorded by renal tests could really be looked upon as a true improvement He thought that the depressor action of the stone had diminished the renal action in the earlier tests and that to this fact was attributable the apparent restoration of function after the stone had been removed

Dr CABOT taking up the point of terminology said that he had confined the termination otomy to mean incision Where drainage temporary or permanent was employed the s ought to be inserted He agreed that nephrostomy was not an operation to be substituted in any way either for the operation of nephrectomy if the other kidney was sound or for the operation of transplantation of the ureter

MOUTH BREATHING AND NASAL OBSTRUCTION

At a meeting of the *Section of Odontology of the Royal* Society of Medicine on April 25th Mr W WARWICK JAMES and Mr SOMERVILLE HASTINGS presented a paper illustrated by slides and models on mouth breathing and *nasal obstruction*

Mr WARWICK JAMES said that for many years Mr Hastings and he had been jointly examining patients suffering from conditions generally believed to be associated with mouth breathing In man nose breathing was normal in all races although the use of the mouth to supplement normal respiration occurred during severe muscular exertion and also in special acts such as yawning coughing sneezing and crying Again under conditions which demanded rapid filling of the lungs with air inspiration was more effective through the mouth than through the nose But the powerful urge to breathe through the nose was present in all individuals It was marked at birth and appeared to diminish in old age He and his colleagues had examined fifty three infants of 1 to 14 days while asleep in the maternity wards of the Middlesex Hospital in every case breathing took place exclusively through the nose It surprised them to discover how very few children who habitually had their mouths open really made use of them for respiration in ordinary circumstances They tested fifty four open mouthed children comprising those who came to the out patient department before operation for tonsils and adenoids and had then been admitted to the children s ward for other conditions In ten of these the mouth was used for breathing by day though at night three of the ten used the nose only the remaining forty four although they had the mouth open by day breathed through the nose Several adults who had their mouth open habitually were tested by day but in each case the nose only was used for respiration In old age especially when the teeth were lost the mouth was often open at night It had been generally concluded that because an individual had his lips apart he of necessity breathed through his mouth but this was not the case Certain abnormal pathological conditions usually described as associated with mouth breathing were therefore more correctly enumerated as accompaniments of failure of one or both oral sphincters When careful examination was made of a mouth breather the conditions were found to be far less simple than would at first appear The presence of a normal negative pressure in the oral cavity during periods of rest was a most important factor the pressure might be slight, but if it failed a sequence of events resulted with all the changes due to mouth breathing The most important changes were associated

with the position and action of the tongue and various deformities could be explained according to the relationship of the tongue to the palate and the dental arches. The anterior sphincter (the lips) was most easily observed and its failure might follow any condition of ill health which produced muscular weakness. In twenty-six out of fifty-two cases of failure of the anterior sphincter investigated there was a history of severe illness or operation in infancy and it would seem that the muscular weakness resulting from this experience initiated the habit. In old age when the musculature had become enfeebled the mouth tended to drop open during sleep. In this case however the posterior oral sphincter (soft palate and tongue) often failed also and mouth-breathing resulted. *During mental concentration the mouth some*times dropped open presumably as a result of muscular relaxation but the condition was only temporary. Failure of the anterior sphincter often occurred in several members of the same family parents and children and perhaps imitation was an important factor. In discussing the possible causes of mouth-breathing the mucous membrane of the nose had to be considered especially that covering the inferior turbinate bones and containing erectile tissue which was liable to swell in conditions of catarrh and also when the atmosphere was warm and moist. Superabundance of clothing by day and especially by night by interfering with normal perspiration might result in the increased need for loss of fluid from the nose and swelling of this erectile tissue. The prone position often resulted also in increased swelling of the mucous membrane.

Mr Warwick James put forward the following conclusions. The urge for respiration through the nose was so great that mouth-breathing was established with difficulty. Oro-nasal breathing was rare. A negative pressure was normally present in the oral cavity and was lost by failure of one or both oral sphincters. This loss of pressure in the mouth was associated with *impaired action* of the tongue lips cheeks and other moulding forces of the jaws and deformities of the jaws resulted from the impaired and misdirected action of these forces. Failure of the anterior oral sphincter was common but did not indicate mouth-breathing. Failure of the posterior sphincter resulted in absence of fixation of the soft palate to the tongue with impairment of the airway. A backward position of the mandible resulted from failure of either oral sphincter and was most marked when both failed. Nasal obstruction by adenoids rarely occurred although associated catarrh and swelling of the erectile tissue might diminish the airway. Finally deformities of the nose and face were rather the cause of nasal obstruction than the result of it.

Mr T. B. Layton remarked that for some time mouth-breathing was understood to be the cause of a particular configuration of the face which characterized large numbers of people in this country. It was now suggested that mouth-breathing was practically non-existent. Adenoids was a term which had been used to denote a *clinical entity*. It was necessary however to go beyond any local lesion in the nose and throat and search more widely for the cause in some conditions affecting the whole body. Mr A. R. Friel described various mechanical lip-exercising devices for inducing closure of the mouth. Mr Lowndes Yates referring to the importance of posture pointed out that whether a child breathed through its nose or mouth depended upon the position in which it slept. Mr E. D. Davis urged closer co-operation between the laryngologist and the odontologist. Mr J. G. Turner considered adenoids a local disease. A large number of children otherwise well grown nevertheless suffered from all the disabilities that adenoids could produce. Dr R. P. Garrow said that the more he had seen of operations in school children for the removal of tonsils and adenoids the less he liked them. A great service would be done if copies of the paper were sent to every school medical officer in the country. Mr Harold Chapman said that in many cases patients were forced to keep their mouths open owing to the position of the teeth.

Mr Somerville Hastings in reply said that very few children breathed through the mouth though many kept the mouth open. What had been called adenoid facies was a condition in which the mouth was open but not necessarily used for breathing. When adenoid tissue became infected it might act as a septic focus and cause nasal obstruction and give rise to trouble in other ways. Mr Warwick James explained that there were many aspects of the subject and the paper had dealt only with local changes. He agreed as to the importance of posture and the value of lip exercises in correcting bad habits provided the device was suitable and the patient properly instructed.

TUBAL GESTATION

A meeting of the Section of Obstetrics and Gynaecology was held on April 15th at the Royal Society of Medicine when a paper was read by Professor H. Leith Murray on tubal gestation.

Professor Murray said that he had made a detailed analysis of 146 cases of tubal gestation. Few of these had exhibited anything very unusual with these exceptions—a case in which a lithopaedion weighing 3½ oz. was found; a case of combined intra- and extra-uterine pregnancy; a case *complicated by bilateral teratomata* and one associated with acutely necrobiotic fibroids. Only four others out of the whole series were really desperate emergencies. In the majority of cases there was a more or less prolonged history of pain and bleeding. The mortality in this series was two, one patient dying of pulmonary embolism on the eighth day and the other of septic pneumonia associated with a pelvic abscess. The average age was 30·5 years. The youngest patient was 20 and the oldest 42. In this particular series the number of ectopic gestations arising in the right tube was greater than that in the left. In 70·5 per cent. the pregnancy occurred in the ampullar portion of the tube. In discussing the termination of tubal gestation the speaker stated that probably a spontaneous cure did occur in many cases by tubal abortion and less frequently by absorption *in situ*. In 146 cases operated on 50 per cent. were almost extruded or appeared likely to have been so if they had been left. In discussing rupture of the tube Professor Leith Murray divided his cases into (1) primary intratubal rupture—that is tubal abortion; (2) primary extratubal rupture either intraperitoneal or intraligamentary; (3) secondary extratubal rupture intraperitoneal or intraligamentary. Of these he considered that primary intratubal rupture accounted for 92 per cent. Not a single case in the whole series was a primary extratubal rupture. Six cases showed secondary extratubal rupture. Turning now to the aetiology of this condition he supported strongly the view that chronic salpingitis and appendicitis were large factors in causing *ectopic gestation and also* called attention to the fact that a reduced fertility was very frequently found in such cases.

In the discussion Dr Wrigley said that an examination of the figures at St. Thomas's Hospital in the last five years corroborated Professor Leith Murray's observation on the incidence of pelvic inflammation in cases of *ectopic gestation*. In very nearly one-half of the cases he had observed obvious inflammatory lesions were present usually in the Fallopian tube of the opposite side.

Mr A Gemmell and Professor Leith Murray then made a communication on two cases of simultaneous intra and extra uterine pregnancy The authors stated that they had collected 214 cases from the literature Although not of great rarity such cases were probably outside the experience of most gynæcological surgeons The two cases were then described in detail In the first case at operation it was deemed advisable to empty the uterus as well as to excise the ectopic gestation but in the second the intrauterine pregnancy was allowed to go to term After a careful analysis of many papers on this interesting subject the authors came to the conclusion that there were no definite criteria on which to base a prognosis of the fate of the intrauterine ovum but where the tubal gestation was removable by operation the prognosis for the intrauterine foetus would appear to be good In twenty one cases an intrauterine pregnancy took place in a patient who already had an ectopic gestation and in this group three of the patients died

LAW AND ETHICS OF ABORTION

At a meeting of the Edinburgh Obstetrical Society held on March 9th with the president Dr James Young in the chair Professor Sydney Smith read a paper entitled

Abortion—a discussion on its social legal and ethical aspects

Dealing with the legal position of the procuring of abortion as defined by the Defence against the Persons Act of 1861 Professor Sydney Smith said that in this Act the words unlawful emptying of the uterus as mentioned specifically This would indicate that the law recognized a "lawful" operation even although it had been held by many authorities that there was no sanction in law for abortion of any sort whether medically justified or not The speaker took exception to this view and said that the law apparently did recognize that abortion might be performed when there was just cause for the operation What constituted a just cause was a difficult matter to decide as there were no legal pronouncements on the point but up to recent years medical men were of opinion that abortion should be carried out only when it was necessary in order to save the life of the mother or to prevent serious impairment of her health Lately however in discussions by leaders of the medical profession other conditions such as nervous debility neurotic and psychoneurotic states had been put forward as good reasons for inducing abortion and with this formidable and elastic list there would seem to be plenty of scope for the complacent physician He did not agree with a number of these reasons Professor Smith then gave a somewhat detailed account of the question of abortion in the time of Plato and Hippocrates and showed how it had become more and more prevalent in the later years of the Roman Empire when abortion was often committed for sheer vanity so that the breasts should not have their shape spoilt by lactation nor the bellies by the scars of pregnancy In Rome it was usually the midwives the wise women and the sorceresses who lived in the lower districts who committed the acts Before the Christian era abortion was rife and was apparently little thought of and wise writers like Aristotle and Plato appeared to have been quite in favour of it In general the early Greeks and Romans looked with approval on abortion for it was considered that the foetus was not a separate being but part of the mother—to be disposed of as she thought fit Throughout the early Christian era there was no law on the subject but the Church always set its face against the practice and had interpreted the commandment Thou shalt not kill as including abortion The Church still objected to abortion and the Roman Catholic Church did not consider that abortion was justified even to save the life of the mother

Lately there had been growing up a considerable body of opinion which was disinclined to bow to the ethics of past generations and individual knowledge regarding sex matters had been greatly increased Also wider facilities were open to a woman now than formerly and her intellectual standard was on a correspondingly higher plane This had equipped her better for the struggle for existence but had not aided her to bear better the strain of reproduction there was a greater tendency to shirk the discomforts of child bearing and, added to this probably a greater tendency towards nervous and mental instability The modern woman had her own point of view and that was that she had control of her own body and if she was not inclined to go through the trouble and inconvenience of child bearing there was no moral right to compel her to do so This view appeared to be quite illogical for though it must be decided to a certain extent by the individual in the control of her own body the State must exercise control over the destruction of its future citizens

The speaker then gave statistics to show how great was the prevalence of abortion at the present time and how impossible it was in this country at any rate to obtain correct figures because only a very few cases of procuring of abortion came to light In Germany there had been a steady fall in the birth rate with a rise in the abortion rate from 16·8 per 100 conceptions in 1913 to 30 per 100 in 1924 Though the law concerning abortion in Germany was similar to the law in this country there had been many discussions on the advisability of advocating the legalization of abortion on grounds other than medical In Russia the incidence of abortion was so great after the revolution in 1917 and the maternal morbidity and mortality so appalling that the Soviet Government in 1920 authorized the operation in certain circumstances In that country abortion could be carried out only by medical practitioners and in public hospitals it still being a crime for any unauthorized person to interfere with pregnancy before abortion could be induced the woman had to make application to a representative board for authorization to be granted In the year 1924–25 254 000 abortions were carried out in Soviet Russia whereas in Leningrad in 1929 58 000 abortions were registered and only 59 000 births In Russia it was found that abortions were desired principally by multiparous women and not by women pregnant for the first time Professor Smith then gave a series of statistics of reasons for the desiring of abortion and compared them with some of the reasons for refusal of abortion by the committees It had been found in Russia that the legalization of abortion had caused a diminution in maternal morbidity and deaths and that the number of patients entering hospitals for uterine hæmorrhage was steadily decreasing and the number of cases of puerperal sepsis was also said to have decreased In the report of the Departmental Committee on Maternal Mortality and Morbidity the committee came to the conclusion that abortion played a serious part in the production of puerperal sepsis and in the causing of maternal morbidity and deaths He considered that we could effect an immense saving in maternal life and health if we could prevent ignorant intervention with pregnancy This could not be secured by repressive measures and that being so the law of abortion ought to be changed so as to allow these unfortunate desperate women to place their cases before some authority who could upon sufficient cause being shown authorize the termination of pregnancy under decent conditions instead of as at present forcing her to place herself in the hands of an ignorant abortionist

Reviews

OLD AGE AND REJUVENATION

Everyone hopes to attain a ripe old age and how best to do so is of perennial interest Sir HUMPHRY ROLLESTON writes of the *Medical Aspects of Old Age*[1] with the charm elegance and wide knowledge which we now take as a matter of course in his contributions to the literature of medicine The present book is the second edition of an expansion of the Linacre Lecture which he delivered at Cambridge in 1922 It opens with a consideration of the duration of life and leads to the *dismal conclusion* that a larger number of average people now reach old age but to some extent this is a survival of the less fit and the average length of life has not been accompanied by an increase in the staying power of the race The real number of centenarians is not yet known The *majority of persons* claiming to have reached one hundred years come from countries where there is no satisfactory system of birth registration and when this has been placed upon a satisfactory basis it will be interesting to ascertain whether centenarians increase or diminish in number The onset and progress of old age is then carefully detailed and it would be well if the attention of the legal profession were drawn to these chapters It would save many social scandals if it were more generally recognized that grave departures from ethical standards in those who have previously led blameless lives was evidence of senile degeneration and not of vice Sir Humphry Rolleston considers the causes of old age and the various *forms of treatment* which have been advocated for rejuvenescence from the time of Brown Sequard to Voronoff and states that the consensus of opinion is adverse to any real and permanent rejuvenation by any of the operative *measures* which have been advanced up to the present time In regard to the pathological hypotheses put forward by Metchnikoff and Arbuthnot Lane he says The safest conclusion is that normal old age or senescence has not been proved to be due to toxins absorbed from the alimentary canal The normal structural changes occurring in physiological old age are discussed organ by organ and tissue by tissue in a manner which would have delighted Sir George M Humphry who was among the first to interest people in centenarians and their habits Finally a chapter is devoted to the masterly description of old age by the poet physician who wrote the first draft of the book known to us as Ecclesiastes or the Preacher—a description worthy to be placed side by side with the picture of the facies hippocratica which has also come down from classical times The book is well illustrated with six pictures of persons reputed to have attained *fabulous* ages and a portrait of Sir Henry Pitman an authentic centenarian who was registrar of the Royal College of Physicians in London There are two indexes the one of authors the other of subjects both full and accurate

The Conquest of Old Age Methods to Effect Rejuvenation and to Increase Functional Activity has been ably translated by Dr and Mrs Paul from Dr PETER SCHMIDT'S German work published in 1928 to which numerous additions up to the late summer of 1930 have been made The author brought out in 1924 an English work on Steinach's operation and the present large volume which is intended for the educated layman as well as for medical readers contains a strong plea for this method of rejuvenation In addition it deals with the history of rejuvenation from ancient times with endocrinology in general and especially of the gonads the methods of rejuvenation and the results A number of case histories are given but successful cases have admittedly been selected for the author considers that there is not any object in reporting failures The demand for statistics of the results of Steinach's operation of ligature of the vas deferens are regarded by the author as evidence of a lack of insight into the peculiar and exceptional nature of the operation and he contents himself by stating that his results in the two years previous to the publication of this work were better than the 77 per cent of successes published in America by H Benjamin in 1926 During the period since 1920 the author has travelled widely and thus finds it difficult to follow up his cases It is frankly admitted that nothing like 100 per cent of successes can be expected Voronoff's transplantation operation is regarded as necessary only when Steinach's vaso ligature is unlikely to be successful For *rejuvenation of women diathermy* is preferable to x ray exposures of the ovaries Though the work covers a wide field the impression left by this advocacy of rejuvenation by Steinach's operation is not convincing

INDUSTRIAL DISABILITY

The assessment of industrial injuries is considered fully in a new book *Accidental Injuries*[2] by Dr HENRY KESSLER The seven hundred pages of this admirable work cover a wide range of subjects and include an account of the relation of trauma to particularized diseases some of which are not included in the British Schedule of Industrial Diseases 1928 While the general reader as well as the expert will find ample matter for reflection the cases quoted as examples and the tabulated material are for the most part American and hence do not enhance the value of the text for the English reader For those conversant with British methods as practised in our courts however the data thus illustrated will be found of value for comparative purposes

The author's main object is to elaborate a technique and method for estimating the extent of impairment caused by an industrial accident—an aim in which he is definitely successful Each portion of the body is described in great detail from various points of view For example in the section dealing with the upper limb the development adaptation and physiology are severally discussed in relation to the limb as a whole The physiological principles are considered with reference to the musculature the joints and co ordination and the elements of evaluation in terms of function Taking the limb as divided into radicals the hand radical is described in terms of hand tools as a hook a pair of pliers and a ring and its function in this respect is illustrated Examples of disability calculations are given The system is *fairly simple and is dependent in some measure* upon mechanical devices which should assist in the elimination of guesswork Similar treatment is accorded to the lower limb as well as to the spine head injuries the thorax the abdomen There are also sections devoted to hernia the genito urinary apparatus the eye throat nose ear and teeth and face Diseases caused or aggravated by injury are considered in detail The system of calculating visual defects will possibly be found a little difficult of comprehension for those who are not ophthalmic surgeons and the statement that a person is industrially blind whose vision is insufficient for ordinary work is rather vague An example of the numerous conditions which may be considered as results of injury may be given from

[1] *Medical Aspects of Old Age* By Sir Humphry Rolleston B CCVO MCB MD Hon DSc DCL LLD Second edition London Macmillan and Co Ltd 1932 (Pp xv + 295 7 plates 7s 6d net)

[2] *The Conquest of Old Age* By Peter Schmidt MD Translated by Eden and Cedar Paul London G Routledge and Sons Ltd 1931 (Pp xvii + 311 40 plates 21s net)

[3] *Accidental Injuries* By Henry H Kessler MD FACS PHILA London H Kimpton 1931 (Pp xx + 718 157 figures 45s net)

the section on the teeth "Loss of teeth, dependent upon their number and position causes a reduction in the masticating surface difficulty in chewing, prolongation of the time necessary to eat a meal gastric disturbances and occasionally loss of strength" Some entities are included such as the traumatic origin of diabetes insipidus endocarditis and heart block the latter occurring nine months after a severe injury to the chest wall The author considers gastric ulcer a possible sequel to epigastric injury The last chapter is devoted to the rehabilitation of the physically handicapped In it is described the evolution of a scheme which began in New Jersey in 1919 its principles being adopted later by forty four States The services rendered to the disabled are physical restoration vocational training, and placement in a job The importance of attaining the maximum physical restoration in each case by surgical methods rather than by training the disabled for a new occupation is insisted upon

In the general section emphasis is laid upon the biomechanics of injury the elasticity of various tissues being described in terms of Young's modulus The characteristics of specific trauma are admirably dealt with and the end results of trauma are described with reference to the skin neurotrophic and neurovascular disturbances fibrosis muscles nerves bones and joints A form of disability rarely if ever taken into account is referred to as prosthetic It appears that in some occupations at least this form of lowered wage earning capacity should be compensatable Another matter which often causes confusion is the determination of permanent disability—when a condition merits this term and when the patient should be considered to have reached his optimum These matters are discussed at some length The text is copiously and clearly illustrated and admirably captioned for reference purposes There is a full bibliography appended to each chapter an excellent index at the end and a clear table of contents at the beginning Statistical data examples and case records are profuse throughout This is in short an admirable and painstaking work the medical (in contradistinction to the legal) part of which should be of great assistance to the large body of practitioners who have to deal with the many phases of the Workmen's Compensation Act and the contracting out system in this country

DIAGNOSIS OF NERVOUS DISEASES

The seventh edition of Sir JAMES PURVES STEWART'S book *The Diagnosis of Nervous Diseases*[4] adds still further to the mass of valuable information contained in the previous editions In form the book remains unique in the English language and among neurological works it is pre-eminent in that its descriptions of clinical syndromes convey clear impressions of patients suffering from the diseases and lesions in question

In his inclusion of the most recent results of experimental neurology—results which he very fairly acknowledges as appealing to him as being correct—the author has brought this work thoroughly up to date It will however be almost universally agreed that some theories are given unmerited currency Thus the explanation of muscle tonus in terms of the sympathetic innervation of non-striated sarcoplastic elements of skeletal muscle has nothing to recommend itself while the explanation of the sensory changes resulting from peripheral nerve damage in terms of separate protopathic and epicritic fibre systems has outlived its usefulness as an hypothesis and should be abandoned It is to be regretted that in practice is maintained of beginning with a chapter on symptomatology and physiology divorced from the diagnosis the material of all later chapters The effect of this arrangement is to force the book into the form which answers the question Given a symptom what are the diseases from which the patient may be suffering? instead of maintaining the more satisfactory sequence of investigation expressed as given a symptom to what disturbance of function is this due where is the site and what the nature of the lesion what are the other symptoms which may be expected—that is what is the disease present? The form here adopted lends itself too readily to the practice of spotting the disease and to a phenomenological attitude toward patients which may provide an impressive display of clinical acumen in out-patient clinics but which is to be discouraged as a method of approach to neurological problems

The book is admirably illustrated and indexed and deserves the same success which previous editions have earned

SULPHUR BACTERIA

The *Sulphur Bacteria*[5] which form the subject of a monograph by DAVID ELLIS are practically an unknown quantity to the medical bacteriologist He dimly recalls that there are such organisms and that they are characterized by the presence of sulphur granules in their ectoplasm but beyond this his knowledge does not go And yet these sulphur bacteria are of abounding interest and importance to man as a perusal of the monograph will show This heterogeneous collection of micro-organisms whose only excuse for appearing together in the same order is the purely physiological one of sulphur metabolism consume sulphuretted hydrogen and produce sulphates as the chief end products of their metabolism The importance of this to man is that the higher green plants on which he relies directly or indirectly for his food require the sulphates for their development As the author puts it in his introduction these organisms constitute a cog in the machinery of life They present other points of interest Apparently sulphur bacteria may multiply in water conduits choking the pipes with large masses of organic matter and rendering the water unfit not only for human consumption but for use in certain industries The sensitivity of these organisms to light is another most interesting question Light has a directive or phototactic influence on the coloured sulphur bacteria and there is evidence that it also has a photosynthetic action the bacterial pigment being concerned in an anabolic process comparable to that performed by chlorophyll in green plants The author who has devoted many years to a study of these bacteria has given us an excellent account of the subject full of interest for the student of biology

SURGICAL TREATMENT OF PEPTIC ULCER

A book entitled Surgery of Gastric and Duodenal Ulcer its Indications and Results[6] by HORTOLOMEI and BUTURE-ANU though written with a distinct surgical bias nevertheless deals fairly with all aspects of the subject The authors from a wide study of the literature and from their own considerable experience come to very definite conclusions as to the province of medicine and surgery in the therapy of peptic ulcer For them *medical treat-*

[4] *The Diagnosis of Nervous Diseases* By Sir James Purves Stewart K.C.M.G. C.B. M.D. Ed. F.R.C.P. Seventh edition revised London: Arnold and Co. 1931 (Pp. viii + 740. 312 figures. 35s. net.)

[5] *Sulphur Bacteria* By David Ellis D.Sc. Ph.D. F.R.S.E. London and New York: Longmans Green and Co. 1932 (Pp. 261. 66 figures. 21s. net.)

[6] *Chirurgie de l'Ulcère Gastrique et Duodénal* Par V. Hortolomei et V. Buturi-anu. Paris: Masson et Cie. 1931 (Pp. 407. 75 figures. 45 fr.)

ment is likely to be most useful in the pre-ulcerous state in allaying the gastritis which precedes and probably conduces to ulcer formation—that is for patients who subject to hyperchlorhydria have suffered at times from indigestion before meals and acidity after indiscretions in diet In the curing of ulcers medical treatment according to the authors has much reduced claims It is usually successful in recent and uncomplicated ulcers but has little effect in chronic ulceration especially where adhesions to adjacent organs are present For the latter surgical methods are indicated The authors divide these into two main groups *indirect* as in gastro-enterostomy (this is more useful for the relief of the secondary pyloric stenosis than for the treatment of the actual ulceration) and *direct* by which the ulcerated area of stomach or duodenum is excised The authors are of opinion that gastro-enterostomy is suitable only for a restricted number of cases that it exposes the patient to numerous complications and that it does not preclude the possibility of recurrence Complete healing is rather to be expected from resection methods and statistics are quoted to show how this view is coming to be accepted more and more by the surgical world The operative mortality was high until anæsthesia with spinal injection or avertin reduced the death rate and freed the surgeon from anxiety about post-operative pulmonary complications The book to which reference is made in a leading article this week will be read with interest and instruction by physicians as well as by surgeons

OSLER WELCH AND OTHERS

Professor W S THAYER has done well to bring together in book form the twenty-four selected addresses and papers which now appear under the title of *Osler and Other Papers* He has many personal friends on this side of the Atlantic and will gain more among the readers of these attractive essays The first three deal with Osler as the author knew him in Baltimore where for fifteen years they were *in almost daily contact and in the rather puzzling story* The medical education of Jones by Smith his hero admittedly appears under the names of Fowler and Guillaume le Oiseleur In a charming analysis of Osler as a teacher and as a human being his simple life and unstudied manner his epigrams love for his fellow men and stern suppression of unkind criticism of others are graphically brought before the reader

Professor Thayer's affection for another of the famous original teachers of the Johns Hopkins University W H Welch finds expression in an after-dinner speech describing this pathologist hygienist and historian of whom he first heard as the ablest physician in America as having taught hundreds of students a religion of charity and of self-restraint a religion of work not of words Of his colleague the late John Howland he writes with graceful enthusiasm and in the memoir of his teacher Reginald Heber Fitz of Boston who in 1886 invented the word appendicitis he remarks It is an amusing thought that of all men Fitz the most careful and accurate should have been the target of irritated critics because of the introduction into medicine of what they regard as an ill-constructed hybrid Among the scholarly addresses the reader will specially welcome those on the Contributions of Pasteur to Medicine and Humanity delivered at the Sorbonne in 1923 the Richard Bright Oration at Guy's Hospital in 1927 Laennec—One Hundred Years After and his Presidential Address to the American Medical Association in 1928 On the Duties and Problems of the Physician

NOTES ON BOOKS

Diseases and Disorders of the Digestive Organs[2] by Dr ADOLPHE ABRAHAMS one of the series of Pocket Monographs on Practical Medicine deserves to be commended for its clarity and common sense Accepting Ryle's classification of dyspepsias the author describes how such cases should be investigated and then proceeds to discuss the different types of dyspepsia in detail The organic diseases of the digestive system are fully described and due importance is given to the treatment of the patient as well as his complaint in cases of functional dyspepsia Each chapter bears the imprint of the author's own experience and practitioners will find much that is useful and applicable in their daily work

Dr FELICE MARTA in his short book *on Gonorrhœa*[3] deals particularly with the public health aspect of his subject though in the later chapters he goes into the question of diagnosis and treatment Like all of those who are engaged in the anti-venereal campaign he protests against the acceptance of gonorrhœa as a trifling disease He points out that it is responsible for a vast amount of ill-health and economic loss notwithstanding the fact that it happens to be a disease which is particularly amenable to public health methods For this reason he discusses the question of prophylaxis and other measures that are capable of reducing its incidence

The fifty-first volume of the *Transactions of the Ophthalmological Society of the United Kingdom*[4] has now been published It comprises the proceedings of this Society and the reports of its affiliated societies during the session 1930–31 As in previous years the communications here brought together cover a wide range of diseases of the eye and the associated neurological conditions The book resembles its predecessors in being highly practical well produced and attractively illustrated

The training of lay inspectors of meat is a difficult one and students must have a working knowledge of the food animals and in particular the position of the various lymphatic glands A booklet[5] by Mr JAMES GOODFELLOW has been produced to assist not supersede practical instruction in this subject It gives a set of diagrams of skeletons topographical anatomy of viscera and cuts of meat showing the position of the main glands of the usual food animals of this country as well as of the horse The diagrams are in colour are well prepared and should be valuable aids to the student

The second edition of LUCAS'S *Forensic Chemistry*[6] has been carefully revised and many of the sections have been rearranged to obtain better co-ordination of the subject-matter This book which is well known to readers interested in criminal investigation describes the various ways in which the chemist may assist in the detection of crime Dealing as it does with the examination of blood stains firearms projectiles forged documents counterfeit coins and poisons and with numerous other conditions in a little over 300 pages no particular subject can be fully described The author however in spite of this manages to place before his readers most of the essential information they require supplementing it by ample references to the literature The section on the examination of firearms and projectiles shows most evidence of revision but we note that no mention is made of the microscopical examination of powder residues which is

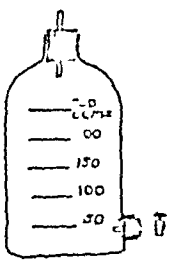
[5] *The Lymphatic Glands of Importance in Carcass and Meat Inspection* By James Goodfellow With foreword by Dr. C. Kirkhope M.D. Ch.M. D.P.H. London The Sanitary Engineering Company Ltd. 1932. (Pp. 29 12 diagrams 2s. 6d.)

[6] *Forensic Chemistry and Scientific Criminal Investigation* By A. Lucas O.B.E. F.I.C. Second edition London Arnold 1932 (Pp. 324 18s. net)

often of more importance than their chemical examination In the identification of bullets and cartridge cases as well as in the detection of forgery and various other matters the author is greatly handicapped in his descriptions by the absence of illustrations without which it is difficult to give any adequate idea of those subjects The book is well printed and there is quite a useful index



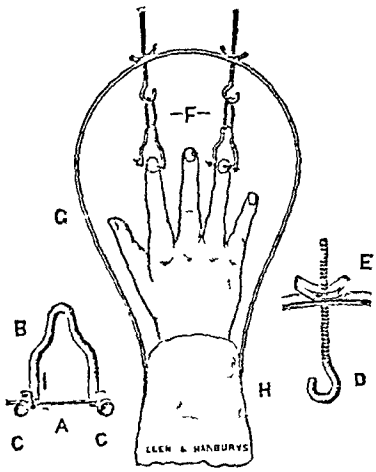
We have received copies of the clinical reports of Queen Charlotte's Maternity Hospital for the years 1925 to 1930 inclusive printed for the hospital by Wilding and Son Ltd Shrewsbury They may be consulted at the Library of the British Medical Association

Reprints of a large number of contributions to medical science originating from the Middlesex Hospital Medical School have now been collated in one volume under the title of *Collected Clinical Papers 1910 31* The book can be consulted at the Library of the Association

PREPARATIONS AND APPLIANCES

APPARATUS FOR ASPIRATION OF FLUID FROM THE CHEST

Dr JAMES MAXWELL (London W) writes The aspirator both illustrated herewith has been made for me by the Scientific Glass Blowing Co and has proved effective and simple to operate It consists of a flat bottomed bottle of about 400 c.cm capacity with two apertures the upper of which is centrally situated and is closed by a tightly fitting rubber stopper which carries a straight glass tube of 6 mm diameter The essential feature of the apparatus is the lower aperture which is situated in the side of the bottle about 1 cm above the base and is closed by a tightly fitting rubber stopper which carries a glass tube guarded by a stopcock as shown in the diagram The bore of the stopcock which is necessarily the narrowest part of the channel should be 4 mm It is a simple matter to fill the apparatus with water after which it is ready for use the upper glass tube is connected by means of rubber tubing with the needle in the chest and the lower drains similarly to a vessel on the floor



The apparatus has been in use at the Royal Chest Hospital for the past year and has been found to possess certain definite advantages It is perfectly stable and can therefore be rested on any convenient flat surface such as a chair or stool thus avoiding the necessity for attachment to a bed rail which is not always convenient The stopcock takes the place of the customary clip and is much simpler to operate for by this means the flow of fluid can readily be adjusted to suit the needs of the individual case It will be noted that the exit tube is situated a short distance above the actual bottom of the bottle thus allowing for the accumulation of fibrinous and other solid material and minimizing the risk of blockage of the exit tube In addition the apparatus is inexpensive and readily portable the tubes and stoppers being carried separately

The apparatus has been employed for the aspiration of all types of fluid from the chest and has been found satisfactory even with empyemata of medium consistency occasionally when there is much fibrin present clotting may occur in the stopcock especially when the fluid is being allowed to run out slowly but the clot can be easily dislodged or the difficulty might be prevented by filling the apparatus with sodium citrate solution instead of water beforehand in cases where there is reason to anticipate clotting It is essential that both rubber stoppers should fit tightly in order to avoid leakage with consequent loss of efficiency

APPARATUS FOR TREATMENT OF FINGER FRACTURES

Mr C MAX PAGE F.R.C.S (London W) writes The common use of skeletal traction is now a well established method for treating fractures of the long bones less frequently phalanges equally applicable to fractures and dislocations of the joints of the hand and of the metacarpals although the latter call for the use of some specialized apparatus The illustration below shows a simple and inexpensive method for applying traction to the fingers The traction appliance consists of a short length of steel wire A which transfixes the terminal phalanx from front to back through the nail I think it is best to employ rustless steel wire for the purpose wire 0·8 mm thick is suitable A straight needle can be employed instead of the wire but on account of the temper of the metal there is a risk of breakage The wire is held in a strut B which is made out of stout brass wire Milled screws CC hold the wire firmly The pull to be exerted in finger fractures is not great and consequently tensioning of the wire is unnecessary The pull is exerted through the bracket G which is firmly held on to the forearm by a light plaster case H The bracket is conveniently made from an aluminium strip about 1·25 cm × 0·5 cm Holes are drilled in the

bracket in suitable positions for the passage of the threaded hook D The position of this hook is controlled by butterfly nut E Steady traction is obtained by the interposition of a stout rubber band or section of rubber tubing F between the hook and the strut B Such an appliance will pull out any recent fracture of a phalanx or metacarpal in which there is overlap and is powerful enough to reduce a dislocation of the interphalangeal joints of some standing On one occasion I was able to reduce a dislocation at the proximal interphalangeal joint which had been present for seven weeks

The appliance has been made for me by Messrs Allen and Hanburys to whom I am indebted for the illustration

THYRAN

Thyran (Bayer Products Ltd) is a preparation of the thyroid gland made by a new method of fractionation evolved by Professor Blum of Frankfort It has an iodine content of 0·4 to 0·6 per cent A point deserving special mention is that the preparation is biologically standardized by a method based on the quantity needed to reduce the weight of a guinea pig by a certain amount within a certain time Biological standardization of activity is a very desirable precaution that is rarely practised in the case of thyroid preparations Thyran is issued in tablets of 25 mg and the clinical reports show that up to ten tablets a day can be taken for three weeks without toxic effects When used in the treatment of obesity it is less apt to produce toxic side actions than are the usual thyroid preparations It has not yet received extensive clinical trial in this country but the reports from German clinics are very favourable

CRYSTALLINE VITAMIN D

Pure crystalline vitamin D manufactured in this country by British Drug Houses Ltd (Graham Street City Road N 1) is now available for general clinical use in the form of radiostol solution and radiostol pellets The former is a tasteless solution in oil of the crystalline vitamin its vitamin D activity is such that one fluid ounce of the solution is equivalent to fifty fluid ounces (2½ pints) of good cod liver oil The dose of this solution ranges from nine to fifteen drops daily Radiostol pellets contain the pure vitamin incorporated in cocoa butter one pellet is equivalent to a full adult dose of cod liver oil

SURGERY AND GASTRIC ULCER

While the respective merits of medical and surgical treatment for gastric and duodenal ulcer are still a subject of active discussion increasing experience by physicians and surgeons has led to a clearer delimitation of the problems involved Although medical treatment was earlier in the field the loss of time involved the difficulty of procuring continuity of suitable diet and the reduced capacity for work by the patient for weeks or months were incentives to seek a quicker and possibly more complete cure by surgical means The physicians are handicapped when asked to produce statistical evidence of good results by the facts that many cases are latent that few workers can submit to prolonged rest and dieting and that in the common absence of a clear and exact diagnosis the determination of after results by following up is difficult Medical treatment should assuredly have a trial when the ulcer is acute and uncomplicated and this trial to be adequate should be sufficiently long In certain cases however surgical intervention is imperative as in perforation Surgery is also indicated when there is doubt about the diagnosis between ulcer and cancer and when the ulcer is complicated by stenosis appendicitis or cholecystitis It is in the intermediate cases particularly of chronic ulcers and those which have resisted simple medical treatment that room for discussion arises not only as to the advisability of operation but as to the surgical measures to be adopted The end to be achieved by indirect methods such as gastro-enterostomy [1] is the earlier emptying of the stomach and the neutralization of the gastric juice by regurgitation of bile and pancreatic secretion In this way a highly acid gastric secretion believed to be inimical to the healing of the ulcer is prevented from accumulating in the stomach Though in many instances highly successful, the published results of these methods indicate a by no means unqualified approval of them The ulcer itself was often not dealt with and therefore apt to give further trouble either by deeper penetration into the wall of the stomach or by contraction during the healing process Further the gastritis accompanying or preceding the ulcerative process produced symptoms and required prolonged medical treatment after the operation Surgical opinion has recently inclined to more direct ways of attacking the ulcer—by excision Partial gastrectomy and if the gastritis also is to be treated a fairly complete removal of the stomach are advocated The effect of such drastic procedures is certainly to get rid of the ulcer and the ulcer bearing organ thus preventing recurrence They have now been tried out over a long enough period to enable some idea to be formed of their immediate and later results

The operative mortality of gastro-enterostomy is generally accepted as low In cases in which this operation is particularly indicated—those with a partial pyloric obstruction from a cicatrized ulcer—the outcome is usually excellent and in the presence of a healing ulcer even without further treatment benefit has been obtained Nevertheless in a general hospital series where patients are often exhausted and have cardio-renal complications the operative mortality may reach 4 to 5 per cent or more In the published statistics permanent healing and freedom from digestive symptoms is obtained in as widely varying numbers as 30 and 90 per cent Hortolomei and Butureanu have followed up 127 cases of gastro-enterostomy operated on by themselves at least four years previously Of these patients 54 per cent were not free from symptoms and thirteen had died of complications in the interval Their immediate operative mortality was 4 per cent so that the immediate and late mortality was 13·7 per cent In a series of 104 cases treated by resection of considerable portions of the stomach for gastric and duodenal ulcer the number of deaths following the operation was five These authors (whose book is noticed in another column) find that late complications are extremely rare, and claim that after convalescence their patients are not obliged to follow any definite course of diet or to restrict their mode of life

That this opinion is widely held is shown by Dr Helge Lublin who has analysed the late symptoms after gastro-enterostomy and operations for resection of the stomach for gastric and duodenal ulcer carried out in the Serafimer Hospital in Stockholm Of ninety-eight cases reported eighty seven had gastro-enterostomy and eleven resection In this series there were ten cases of true recurrence (a false recurrence —that is a second or multiple ulcer—being excluded) and ten cases of peptic jejunal ulcer all of them in cases of gastro-enterostomy In a further fifty five cases of which nine had had a Billroth II resection gastric symptoms occurred though evidence of ulcer was lacking These symptoms which usually arise immediately after operation included among others a feeling of weight or dragging pain in the epigastrium shortly after meals vomiting—often bilious—and wasting In case of definite ulcer or where ulcer is presumably the cause of the symptoms these appear much later In a further twenty cases the symptoms were mainly intestinal in the form of colic flatulence constipation and diarrhoea of these two had had resection of the stomach and the remainder gastro-enterostomy The main factors behind the digestive disturbances are probably (1) that normal gastric digestion is reduced by the rapid emptying of the stomach and to a less extent by the lowered acidity and (2) that normal intestinal digestion is hampered by the unphysiological way of emptying the stomach

[1] Leslie Skert *British Medical Journal* 1931 i 475

[illegible] Nov 1931

and the consequent impaired mixture of gastric chyme and duodenal juice. In Dr. Lublin's series of cases the digestive disturbances after complete resection of the stomach, are generally of mild character, if indeed appreciable at all. A striking result in her analysis is that in two-thirds of the cases there was evidence of some degree of non-haemorrhagic anaemia—a sequel to both gastro-enterostomy and resection. The causation of this anaemia is obscure, but is probably to be sought in the disturbances that the operation brings about in the physiology of the digestive organs. Where exclusion of the pylorus has been carried out by ligation or as part of the resection the liability to anaemia appears to be greater.

It was the surgeons who in generation ago drew the attention of the medical world to the clinical features and common occurrence of duodenal ulcer, and during the past thirty years the scope of surgery in the treatment of gastric and duodenal ulcer and the indications for the various operative procedures have become more defined. Improvement in surgical technique has led to more successful results. It may be, however, that greater skill in diagnosis will enable medical treatment to be instituted earlier and in the pre-ulcerative stage, so that the next generation may see medical treatment sufficient and surgery adopted only in neglected or complicated cases.

WORK AND THEORY

The momentous results of Pasteur's discoveries are apt by their very brilliance to distract attention from other aspects of his life and activities, which have a bearing on the prosecution of scientific research. For example his attitude in approaching problems and the principles which underlay his methods of solution deserve a closer attention. Considering the uniform success of his researches it would seem that his methods must have special features peculiar to himself, for it is remarkable that he never undertook an investigation without bringing it to a successful issue, a record which probably few whose work covers fields of any considerable breadth are able to boast of. Whether the problem related to crystallography, to abnormal fermentation of wine, beer, or vinegar, to spontaneous generation, to asepsis, chicken cholera, anthrax, or hydrophobia, the result was in every instance an unequivocal solution. It may be said that this was due to his extraordinarily clear vision, an expression of his genius, and therefore *imitable*, but, admitting this, the whole gospel of scientific research is double unfolded in Pasteur, and a study of his methods must both hardly fail to reveal principles useful to would-be eminently endowed than he was [illegible] requires special qualities.

required what may be termed a "belief in achievement." This he retained throughout his career and it was undoubtedly a stimulating influence in his undertakings. He believed that patient, persistent work animated by a simple aim and single intention if unremittingly pursued, would inevitably be rewarded with achievement. He had no doubt of this. "You have but to walk forward," he says, "and your task will achieve itself." But he also came to realize that work pursued on this principle needed vitalizing if it was to be fruitful and he recognized theory as being the required vitalizing agent. The path of scientific inquiry was to be illuminated by theory, mere demonstration being of little use as an aid to knowledge. A scientific discovery by itself had no more than the merit of its existence, whether a chance observation or the solution of some detached problem; it remained a dead letter unless vitalized by theory which alone was capable of calling into being and developing the spirit of invention. "Without theory practice is but routine born of habit." The point emphasized seems to be that the solution of a problem should always be viewed in the light of a larger conception—a good rule applicable to other than scientific problems, to ideas in general. Finally, Pasteur was fully alive to the fact that unrestrained theory led to diffuseness if not to actual error defeating its own ends, and he laid down a stringent rule in regard to its employment. Reference was made to this in his speech at the inauguration in 1888 of the Pasteur Institute in Paris and his words receive emphasis from the importance of the occasion. "Your enthusiasm," he said, "which is the fruit of your early days keep it, my dear collaborators, but let it ever be attended by a rigorous self-control. Advance no theories, nothing which cannot be proved in a manner simple and decisive." Pasteur's uniform success was, we may be sure, at least partly due to his adherence to the principles alluded to, and as regards the last in particular, he never advanced a step into the realm of scientific assertion unless the incontrovertible reasons for so doing were already in his possession. Pasteur had no objection to an honest belief, writing to Pouchet, he says: "I think you are wrong not in believing in spontaneous generation, but in it is difficult in such a case [illegible] desirable precaution that ideas) but in affirming case of thyroid preparations generation." [illegible] tablets of 25 mg. and the clinical [illegible] up to ten tablets a day can be taken

The fa[illegible] weeks without toxic effects. When used in the co[illegible]ment of obesity it is less apt to produce toxic side actions than are the usual thyroid preparations. It has not yet received extensive clinical trial in this country, but the reports from German clinics are very favourable.

[illegible] Biological

CRYSTALLINE VITAMIN D

Pure crystalline vitamin D manufactured in the country by British Drug Houses Ltd. (Graham Street, City Road, N.1) is now available for general clinical use in the form of *radiostol* solution and radiostol pellets. The former is a tasteless solution in oil of the crystalline vitamin; its vitamin D activity is such that one fluid ounce of the solution is equivalent to fifty fluid ounces (2½ pints) of good cod-liver oil. The dose of this solution ranges from nine to fifteen drops daily. Radiostol pellets contain the pure vitamin incorporated in cocoa butter; one pellet is equivalent to a full adult dose of cod-liver oil.

[illegible] TREATMENT OF FINGER FRACTURES

Mr. C. Max Page, F.R.C.S. (London, W.) writes: The common use of skeletal traction is now [illegible] method is for treating fractures of the long bones [illegible] changes equally applicable to fractures and dislocations [illegible] of the hand and of the metacarpals although [illegible] use of some specialized apparatus. The [illegible] traction shows a simple and inexpensive method for [illegible] to the fingers. The traction appliance consists of a short

PERNICIOUS ANAEMIA

The view that a primary progressive anaemia is a disease separable from the anaemias following say cancer of the stomach has been accepted by clinicians since the time of Addison's original description. A century's work and study have differentiated several other similar conditions—such as sprue and the presence of the tapeworm *Dibothriocephalus latus*—leaving a clinical entity known in this country as primary Addisonian anaemia and on the Continent as Biermer's anaemia. It was Biermer who first introduced the term 'progressive pernicious anaemia'. A useful analysis of a series of 117 cases of pernicious anaemia has been published[1] from the records of the first medical clinic of Serafimerlasarettet in Stockholm. Dr. Birger Strandell, who collected the material, has had the great advantage of examining the carefully recorded clinical notes and films made from the blood in each case. Basing his diagnosis on the blood picture therefore he has accepted only cases showing the characteristic features of pernicious anaemia. Of the total number of patients about half were men and 60 per cent. were above the age of 50. Of the general symptoms languor was the commonest and change of colour—pallor with more or less of a tinge of yellow—was almost constant. Loss of appetite, especially for meat was present in three quarters of the patients and emaciation in about the same proportion. Nearly all cases had at some time of their course a rise of temperature. Of this series only 12 per cent. showed evidence of combined degeneration of the cord and about 40 per cent. had retinal haemorrhages. Symptoms related to the digestive system—such as sore tongue, vomiting, abdominal pain, and trouble with the bowels—were common. In 30 per cent. of the cases vomiting, eructation, or diarrhoea occurred more than five years before the anaemia supervened. Special interest attaches to the association of achylia gastrica with pernicious anaemia; this was found in ninety-five of the ninety-six cases of this series examined with test meals. The exception was a farmer aged 54 whose blood picture was typical though free hydrochloric acid was present in the test meal. The patient died of anaemia. Necropsy revealed ulceration of the ileum and jejunum and the characteristic bone-marrow changes of pernicious anaemia. In all the other cases, even when examined in the remission stage, achylia was invariably found; in these instances histamine was also used. The addition of achylia was always found in these methods indicate a way in which the examination approval of them. The ulcer itself are there were any with and therefore apt to give further trouble of pernicious deeper penetration into the wall of the stomach. But contraction during the healing process. Further the gastritis accompanying or preceding the ulcerative process produced symptoms and required prolonged medical treatment after the operation. Surgical opinion has recently inclined to more direct ways of attacking the ulcer—by excision. Partial gastrectomy and if the gastritis also is to be treated a fairly complete removal of the stomach are advocated. The effect of such drastic procedures is certainly to get rid of the ulcer and the ulcer bearing organ thus preventing recurrence. They have now been tried out over a long enough

[1] Pernicious Anaemia. Acta Medica Scandinavica, 1931, vol. lxxvi, p. 423.

of the nature of a deficiency disease. The changes in the type of blood cells present in the circulation and the early involvement of the stomach would favour the latter theory, and the rapid response of patients to liver products and stomach extracts would point to the same conclusion. The beneficent influence of liver or liver extracts in a disease previously regarded as almost certainly fatal has led to a renewed hopefulness in treatment. As shown by the author's figures, of 117 patients treated in hospital 62 died within a year of their first admission. Nevertheless the course of the disease in a number of cases has been remarkably favourable. In Dr. Strandell's series there were ten cases of cryptogenic pernicious anaemia in which the duration without treatment by liver or stomach was over seven years, and in three more this was probable though not proved. One case had run a course of eighteen and a half years, and the patient had kept in good health for close upon sixteen years without treatment which would seem to be the longest observed remission hitherto recorded in the literature. In Cabot's series of 1,200 cases of pernicious anaemia only 3 per cent. showed a duration of more than seven years. It would seem however that a fair proportion of Dr. Strandell's cases ran a favourable and prolonged course even before the modern treatment with liver and stomach. Thus the statement in most textbooks that a prolonged course of the disease only occurs in exceptional cases may require revision. It is of interest to note that from 1913 it has been the practice in Stockholm to treat patients with large amounts of meat in addition to arsenic and dilute hydrochloric acid. The quantity of meat given daily was 200 grams a head, *in some cases more, in moribund cases minced meat*, and meat extracts were given by stomach tube. The best prognosis appears to be found among men below 50 years of age; seven out of twenty-five (28 per cent.) have run a course of seven years or more.

'EUTOPOTROPISM'

The sense to know where you are well off and go there, the sense to find the fit place, is the definition given by Professor A. C. Lane[1] to the word eutopotropism which he has coined. It apparently means something more than adaptation to environment. The inability to eutopotropize (one word unfortunately leads to another) has plagued the post-war generation and the host of modern psychologies bear witness to this fact. Had Professor Lane been a physician and not a geologist he might have hesitated to advise his audience to go "where you are well off and to the place for which you are fit." The advice is simple and so he says sensible. But it has all the dangerous wayes of the slogan. Commentators on the text constipate are sure put forward many and various resection of the side word fitness and would no entero-tomy. The ramifications that might arise when disturbances are probably [illegible] well off and [illegible] digestion is reduced by the rapid emptying of the stomach and to a less extent by the lowered acidity and (2) that normal intestinal digestion is hampered by the unphysiological way of emptying the stomach.

[1] [illegible] Nature and Society, 1931.

Dr J Vergely has uttered a complaint under the title of "Medecins amateurs" which has recently been echoed in our own columns under the more prosaic heading of *Doctors and district nurses*." Every man or woman who has had a toothache or any of the other minor ills the flesh is heir to is liable to become an amateur physician—given the opportunity. Dr Vergely however refers to the women who became temporary nurses during the war. Their appetite has grown upon what it fed, and, believing themselves intuitively endowed with medical knowledge, they carry on "*une sorte d'exercice illegal de la medecine*" taking advantage of the credulity shown by many patients. To protect themselves against these invaders Dr Vergely tells his fellow practitioners that they have to rely on their own good faith, their conscience, and the appeal to the natural good sense of their patients. Pessimistically he admits that this last argument is the one least likely to prevail. In our issue of March 5th (p. 456) a whole time medical officer of health in an industrial area wrote suggesting that there should be fuller co-operation between nurses and doctors, as in his experience the treatment of many minor ailments which could be more efficiently carried out by a nurse was left to the relatives of the patient. Subsequent correspondence has shown that opinion on this matter is divided the balance on the whole appearing to weigh against the district nurse. The chief complaint is that she 'does too much' that she diagnoses and treats diseases coming within the province of the doctor and that there is a danger of her becoming a *femme-medecin, amateur*. On April 2nd 'Another Devonshire G.P.' wrote to say that the district nurse is one of the general practitioner's staunchest allies,' and praised her assistance in midwifery cases other doctors condemn her lock stock and barrel. There is no smoke without fire and it seems that a district nurse at times cannot resist the temptation to apply the knowledge she has but which should legitimately not be put into effect. Co-operation between doctor and nurse would seem to be a purely individual matter and to the remedy of appealing to the natural good sense of the patient recommended by Dr Vergely should be added that of appealing to the same good sense of the nurse.

BODY MECHANICS EDUCATION AND PRACTICE

A conference on child health and protection called by President Hoover, was held at the White House, Washington, in November, 1930. The report of its subcommittee on orthopaedics and body mechanics is now published under the title of *Body Mechanics Education and Practice*[1], body mechanics being defined as 'the mechanical correlation of the various systems of the body, with special reference to the skeletal, muscular and visceral systems." The purpose of the subcommittee was (1) to investigate the incidence and cause of poor body mechanics, (2) to consider what is being taught about this subject and decide what should be taught, (3) to develop a plan for in this connection ved methods of training in good published biography nd correction of faulty body Pasteur, brought 'reliminary work was done in seriousness and earnes ad special data. By sending stance or from the na

[1] The Century Company London

[1] *The Genius of Louis Pasteur*) A Ousley Ltd (12s 6d)

questionnaires to paediatricians, orthopaedic surgeons, medical schools, and physical training colleges a mass of representative opinion was obtained on questions such as the importance of and scope for, training in body mechanics. Appendix I is a report of group training in posture in an elementary school in Massachusetts, and includes descriptions of methods of examining children and keeping records of their physical condition. A series of silhouettes show the salient features of good and bad postures in different physical types, and important points are tabulated below the diagrams. Appendix II contains a useful plan of a course in physical education for elementary and intermediate schools and also a list of books on the subject. The two main conclusions reached by the conference were (1) That body mechanics should be an integral part of study in medical schools and the basic principle of physical education. (2) That training in body mechanics should be compulsory for the children of the United States of America and opportunity given for corrective training in those with faulty body mechanics. The conference set itself difficult tasks and should accomplish much for the welfare of children. The genealogical tree showing the origin of its committees is rather overwhelming and we are inclined to think that equally good work could have been done by fewer than the hundred and twenty nine subcommittees which evolved from the original planning committee.

NEW TUBERCULOSIS LABORATORIES AT THE PASTEUR INSTITUTE

The continuous increase in the tuberculosis work carried on at the Pasteur Institute, Paris, particularly in the demands made for tuberculin, for Boquet and Negre's complement-fixation antigen and for B.C.G. vaccine has rendered necessary an extension of the already existing inadequate accommodation. It was considered desirable to group all the tuberculosis services together and accordingly a new block of tuberculosis research laboratories has been erected in the gardens of the institute. A description of these laboratories, which are now completed, is given in a recently published pamphlet[1]. Those who are interested in the construction of laboratories will do well to study this publication which contains numerous illustrations or, still better to pay a visit to the new building and judge for themselves the excellence of its design and equipment. When it is considered that the estimated cost was only eight million francs, a sum which before the fall of the pound was equivalent in English money to about £70,000, it is impossible to do other than admire the French for their architectural and engineering efficiency and envy them for being able to erect a building at a cost probably about one-third of what would be required in this country. One of the main objects in view was to afford suitable laboratories for the preparation of B.C.G. vaccine, and to separate these entirely from the remainder of the laboratories in which work involving the use of virulent tubercle bacilli was to be performed. Briefly, the building is of rectangular form and is 70 metres in length. There are three main floors—first second and third—but, owing to the fact that the frontage on the Rue Falguiere is considerably higher

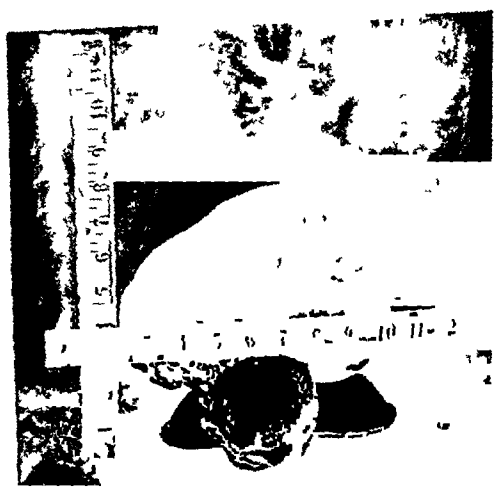

FIG. 1.—Naked eye appearance of tumour.

than that on the gardens of the Pasteur Institute a mezzanine and a ground floor have been rendered necessary on the side facing the institute These two lower floors are given over to the accommodation of normal and infected animals together with a post mortem room for experimental animals and a dark room for radiological examinations The type of animal cage designed by Dr Guerin is of unusual interest consisting of a solid sheet iron box 40 cm in all directions, coated with aluminium paint and provided with a removable grilled lid fitted with a simple bayonet catch The cages can be sterilized by steam and the peat moss which is used as an absorbent, can be burnt in an incinerator The first floor is given up to work on B C G On the second floor there are research laboratories one of which is allocated to foreign visitors wishing to carry out work on tuberculosis Laboratories for the preparation of tuberculin and of the Boquet and Negre antigen together with those for chemical research and for morbid anatomy occupy the third floor Whatever the merits of B C G may be it is evident that in its preparation no amount of care can be too great in order to avoid the dangers inseparable from the use of a living vaccine The council of the Pasteur Institute may be sincerely congratulated on erecting suitable laboratories for this purpose and affording ample accommodation for the conduct of research in all aspects of tuberculosis There is little doubt that the new laboratories will prove a further attraction to the numerous scientific workers from all parts of the world for whom the Pasteur Institute with its great traditions and its admirable record of research holds out the promise of scientific training and achievement

MEDICAL PORTRAITS AT THE R.A.

The one hundred and sixty third exhibition of the Royal Academy opened to public view on Monday It presents specimens of the work of many schools of thought and some abrupt contrasts in modes of pictorial expression but we will not venture to distinguish between the meritorious and the meretricious The medical portraits of which there are several in good positions show no tendency to break away from established practice in each of them the artist has evidently set out to make his subject recognizable at a glance In the principal room will be found Sir Arthur Cope's oil painting of Dr Alfred Cox which is destined for the British Medical Association's headquarters It reveals Dr Cox in meditative mood as so many members must have seen him on the platform or at committee meetings when business is not moving quite as fast as it might The doctor's gown gives an unfamiliar splash of colour but this is the man we know with the considering look that presages a remark very much to the point Near it is an admirable likeness of Professor Thomas Sinclair of Belfast by George Harcourt who has also painted the presentation portrait of Miss Lloyd Still matron of St Thomas's Hospital which hangs in the same gallery In the next room attention is held by Mr J S A Berne's lifelike picture of Professor Blair Bell seaman, white coated against a blackboard and holding a lecturer's wand Here the artist has produced a bold effect without bright colours in contrast to the portrait by Dermod O'Brien of Dr Crofton draped in the vivid scarlet of an Irish M D robe Patient search among the sculptures will discover Percy Metcalfe's design for the Hughlings Jackson medal and in the south room a miniature of Mr C W Proom by Hilda Bowyer The architectural room has some drawings and plans of interest to medical visitors

TUBERCULOSIS SCHOLARSHIPS IN ROME

The Italian Fascist National Federation against Tuberculosis is placing at the disposal of the International Union against Tuberculosis two competitive scholarships at the Benito Mussolini Institute in Rome These scholarships of a value of 6 000 lire each plus board and lodging are intended to enable foreign medical practitioners to reside at the Institute for the purpose of following a course of studies This stage of eight months will correspond with the academic year (from November 15th to July 15th)—namely eight months interrupted by the usual holiday periods The scholarships will preferably be awarded to young physicians who are already familiar with tuberculosis problems and who wish to improve their knowledge of this branch of medicine The kind of work undertaken at the Institute will be subject to an agreement between the director and the candidate Publication expenses resulting from this work may be defrayed partly or entirely by the Institute The scholarships will be awarded by the executive committee of the International Union in September next Names of candidates with particulars of their age qualifications and professional experience must be received by the secretariat of the Union not later than July 15th No candidature will be taken into consideration unless it has been forwarded by a Government or Association belonging to the International Union All applications from Great Britain and Northern Ireland must be forwarded through the National Association for the Prevention of Tuberculosis they should be sent to the secretary N A P T Tavistock House North Tavistock Square W C 1 by July 10th

The next session of the General Medical Council will commence on Tuesday May 24th at 2 p m when the President Sir Norman Walker M D will take the chair and give an address The Council will continue to sit from day to day until the termination of its business

CENTENARY MEETING OVERSEA VISITORS

All overseas delegates and guests and other members from overseas intending to take part in the Centenary Meeting of the British Medical Association next July who desire hospitality for themselves and their wives (if accompanying them) should communicate immediately with Sir Cyril English K C M G 5 Park Street London W 1

Masonic Welcome

The Motherland Lodge [illegible] a special meeting on Monday July 25th to welcome [illegible] Masonic Centenary Meeting [illegible] Communications should be addressed to the secretary of the lodge Lt-Col H Vaughan (Travellers' Club Pall Mall S W 1) Cheques and postal orders should be made payable to the Masonic Centenary Fund

BRITISH SEA COAST RESORTS

CONFERENCE AT BOURNEMOUTH

The third regional conference arranged by the British Health Resorts Association was held last week end at Bournemouth under the presidency of the Mayor, Alderman P M Bricker. Its outcome was the formation of a local branch for the southern region (western section) comprising Weymouth Swanage Poole Bournemouth and Christchurch. Following the pattern of earlier conferences two business sessions were held.

Sir Thomas Oliver took the chair at the morning session on April 30th in the Town Hall and the Mayor welcomed the medical men who were visiting Bournemouth in order to show their interest in this movement. A message from Lord Meston president of the association expressed regret that distance at Geneva prevented him from taking part in a meeting which would mark another milestone down the road to success. In his introductory address Sir Thomas Oliver said that it was their task to draw public attention to the advantages of the health resorts such as Bournemouth so that fuller use could be made of them. The great variety of climate at the principal coastal stations of Britain provided wide opportunity for practical application of the new science of climatology to the treatment and prevention of disease. In past years the choice of a resort had been largely haphazard and without special reference to the nature of a patient's illness. The need of health stations for all classes was likely to increase rather than diminish.

Dr K Lorimer Fox chairman of the medical advisory committee in a paper on Centres of convalescence emphasized the need for a central building at every resort equipped with some simple form of medical baths and designed to include means for recreation in all weathers. England had led the way for over a hundred years in the establishment of convalescent homes. The problem of convalescence in its widest sense was of great importance and the climatic stations of Britain were only at the beginning of what they might accomplish on behalf of our crowded urban populations. Dr J Brownlee Alexander speaking on local advantages to the convalescent patient mentioned the importance of psychical influences which reinforced the benefit of a visit to the seaside. Dr H Gordon Smith medical officer of health for Bournemouth followed with a paper on the effect of climate in therapeutics and Dr Harold Simmons spoke on Bournemouth as a health resort.

The discussion that followed was opened by Dr K A Young and continued by Colonel W Byam who summarized in order of frequency the excuses given by patients for not staying at home resorts as follows: (1) the climate (2) English cooking (3) unfashionableness of home resorts (4) need of change of scene and occupation (5) lack of amusements (6) ban on gambling (7) greater cost of a holiday here (8) absence of facilities for a cure. It seemed to him that a centre where modern methods of diagnosis and treatment could be applied was a necessity in every health resort. Dr A Cawadias touching on the international aspect of the problem said that some hotels in British resorts could compete with any on the Continent and that all had far better sanitation. The need was for data concerning the action of certain climates on certain conditions of health and disease.

At the afternoon session Dr Alfred Cox took the chair and in his opening remarks discussed the reasons that led many people to go to the Continent rather than to home resorts. One was that they got better value for their money. He urged that the seaside resort industry should become fully organized and in this the co operation of the medical profession was indispensable. Hitherto there had been no specialized intensive study of climatology as applied to health. One of the chief aims of the present movement was to persuade local practitioners to get down to this task so that the profession throughout the country might know what places were suitable for particular cases and how their patients would be treated when they got there. His experience was that local doctors could be stimulated into activity if they felt that a movement was in the interests of the public.

Colonel R H Elliot chairman of the executive committee in a paper on the human side of the movement outlined the organization proposed for putting this work on a permanent basis. Two important questions were the setting up of a central bureau and the compiling of an authoritative reference book on British health resorts. It was a great encouragement to him to be standing on the platform that afternoon between the President of the British Medical Association (Dr W G Willoughby) and the Medical Secretary and to be supported by the Chairman of Council (Dr Brackenbury). The main purpose of the movement was to organize the national assets in the way of seaside and other resorts, and to let everyone in Britain and outside know what these assets were. It was proposed to form a council composed of fifty medical men and fifty laymen meeting twice a year with the administrative work in the hands of an executive committee behind which as the backbone of the movement was the advisory medical committee acting as a link between the medical profession and all the other interests concerned.

Dr W S C Copeman honorary secretary of the medical advisory committee gave further details about the medical policy of the Association and submitted resolutions formally constituting a new branch for the local area.

On Saturday night the guests were entertained at a banquet in the Pavilion given by the Bournemouth Corporation. The Mayor proposed the toast of The British Health Resorts Association, and Sir Thomas Oliver replied. The health of the guests was proposed by the Deputy Mayor and Dr W G Willoughby responded in his happiest vein. Sunday was given up to a visit by road to Weymouth where the Mayor presided over a luncheon party at the Gloucester Hotel and to Sandbanks where the visitors were received by the Mayor of Poole at the Haven Hotel.

The next conference of the association will be held at Tunbridge Wells on May 20th.

LONDON VOLUNTARY HOSPITALS COMMITTEE

SECOND ANNUAL REPORT

The London Voluntary Hospitals Committee appointed by the voluntary hospitals for the purpose of consultation with the London County Council as provided by Section 13 of the Local Government Act 1929 has issued this week its report for the year ending March 31st 1932. During the period under review the committee has been in constant communication with the Central Public Health Committee of the London County Council. Important decisions have been arrived at.

Acting upon the suggestion of the Voluntary Hospitals Committee it has been agreed between the two committees to conduct a survey of the medical surgical and ancillary services in the county. The Standing Committee of the Metropolitan Borough Councils has expressed its willingness to co operate by supplying information relating to services for which the borough councils are responsible. The survey which is in progress will show the number of institutions in each area distinguishing between municipal and voluntary the accommodation available for each class of case the staffing of each institution the area from which patients are drawn the facilities for extension the need for further developments and other useful details. The task is one of considerable magnitude as the survey involves institutions comprising some 100 000 beds. It is however hoped that it will be completed in the course of the next two months. It will provide the first authoritative description of the medical surgical and ancillary services of the county. The need for co ordinated information is obvious. Without it the

best use cannot be made of the facilities provided by each system overlapping cannot be avoided and economical effective progress is impossible Further without such a survey it is impossible to give effect to Section 13 of the Local Government Act 1929 which provides for consultation between the municipal authority and the voluntary hospitals within its area

Discussions have taken place between the two committees concerning medical education As a result the Public Health Committee decided to continue existing arrangements between individual teaching hospitals and municipal hospitals The extension of these arrangements is now being considered by both committees and it is hoped that some more thorough and satisfactory means may shortly be devised which will enable a teaching hospital to be linked to a municipal hospital if and when desired The voluntary hospitals have welcomed the decision of the Public Health Committee to appoint salaried short term resident house physicians and house surgeons for service in municipal hospitals being of opinion that these appointments will provide valuable post graduate experience

The two committees have also discussed various proposals made by the County Council for increasing accommodation at certain municipal hospitals and for the establishment of special units such as those for thyroid cases and plastic surgery Projected scales of salaries and wages in municipal institutions have also been the subject of consideration Statements regarding these matters have from time to time been issued to the committee's constituent hospitals

CONSTITUTION OF THE COMMITTEE

The London Voluntary Hospitals Committee is composed as follows

Lord Riddell Royal Free Hospital (*chairman*)
Dr Geoffrey Evans St Bartholomew's Hospital (*honorary secretary*)
Mr A Lawrence Abel F R C S Cancer Hospital
Mr F Arnold Baker Seamen's (Dreadnought) Hospital
Lady Barrett M D Mothers' Hospital of the Salvation Army
Mr O N Chadwick Healey Hospital for Sick Children
Mr Thomas Clipham Belgrave Hospital for Children
Lieut Colonel Clement Cobbold Cordon Hospital
Dr Edmund H Colbeck Cit of London Hospital for Diseases of the Heart and Lungs
Captain the Right Hon C C Craig St George's Hospital
Mr Robert Davies Colley F R C S Guy's Hospital
Professor J S Dudgeon F R C P St Thomas's Hospital
Mr Arthur G Ferard Victoria Hospital for Children
Mr Charles Gibbs F R C S London Lock Hospital
Sir Henry Gooch King's College Hospital
Mr F J Pearce Gould F R C S Middlesex Hospital
Dr A M H Gray University College Hospital
Dr Philip Hamill Metropolitan Hospital
Captain A M Hughes Seamen's (Docks) Hospital
Mr A P B Irwin St Thomas's Hospital (replacing Sir George Makins)
Sir Henry Jackson M P Bolingbroke Hospital (*treasurer*)
Dr J M H MacLeod Charing Cross Hospital
Mr M S Mayou F R C S Central London Ophthalmic Hospital
Mr F Vernon Miles Hampstead General Hospital (*honorary treasurer*)
Mr Robert Milne F R C S London Hospital (replacing Mr H S Souttar)
Mr Arthur Morley Royal National Orthopædic Hospital
Sir Ernest Morris London Hospital
Mr Gilbert C Painter Royal Northern Hospital
Mr D Denham Pinnock F R C S National Temperance Hospital
Dr Arthur Porter Evelina Hospital for Children
Dr Harold Pritchard Miller General Hospital
Mr D W Ross F R C S Central Evangelical Hospital
Dr F Bellingham Smith Queen's Hospital for Children
Mr Waddington Stansfeld Hospital for Consumptives
Mr Thomas G Stevens F R C S Hospital for Women
Mr Alan Taylor West London Hospital
Sir William H Wells West London Hospital
Mr J F Wetenhall West End Hospital for Nervous Diseases
Mr Francis F Wetherall Guy's Hospital
Dr C M Wilson St Mary's Hospital

Ireland

North of Ireland Government and Hospital Administration

Sir Dawson Bates Minister of Home Affairs stated at Dungannon recently in connexion with the proposed erection there of a new hospital to replace the workhouse building that a view had been propounded in certain quarters that there should be less devolution of hospital administration and more centralization in his opinion this view was wrong It was important that a Central Government should delegate powers to local authorities as this had been found to be productive of better results The policy of the Government was to try to promote friendly and happy relations between local authorities and it would not turn down any reasonable proposal which they brought forward He was fully aware of the disadvantages under which the local hospital authorities laboured at present In some places the tendency was for local authorities to accept the inevitable but in Dungannon Dr Mann and his staff under difficult circumstances had accomplished good work When the joint committee had decided on a suitable scheme they could present it to the Government who would examine it carefully The councils he believed could rely on the assistance of the Government in bringing the scheme to fruition Referring to the future policy of the Government with regard to the Poor Law system he said it was the Government's desire to brighten up the lives of those who through no fault of their own had to seek admission to the workhouse In the old days families coming into the union had been separated but the Government aimed at abolishing that obsolete system and establishing comfortable regional homes

Royal National Hospital for Consumption

At the annual general meeting of the governors of the Royal National Hospital for Consumption the report stated that the treatment known as artificial pneumothorax had been more extensively used during the past year and had proved of great benefit to those patients who were suitable for it Sanocrysin or gold treatment had again been given in a number of cases either alone or in conjunction with artificial pneumothorax and good results had been obtained The report called attention to the heavy expenses of the hospital during 1931 and appealed to the public for increased help Only a very small portion of the cost of the x-ray installation appeared in the accounts for the year and nearly £1 000 would have to be found out of the ordinary income for maintenance Dr T G Moorhead President of the Royal College of Physicians in Ireland in his report stated that satisfactory results had been obtained during the year In over 73 per cent of early cases great improvement had been effected while in twenty two cases a complete cure had apparently resulted He would like to call attention to the forward policy which the medical staff had adopted During the last few years anonymous had tried extensively with encouraging results The hospital was now equipped with a thoracoscopy apparatus and pneumothorax treatment on [illegible] possible He sincerely hoped that the committee [illegible] offices would find some means [illegible] of pneumothorax treatment [illegible] The patients who lived in Dublin [illegible] could easily be dealt with [illegible] where special [illegible] twas to be given [illegible] free [illegible] in the [illegible] day He hoped [illegible]

be fitted up for the treatment of bone and other forms of tuberculosis occurring in adults there was a great lack of provision for such treatment in the Irish Free State It had lately been rumoured that in many of the counties of the Saorstat, the county councils proposed to establish their own sanatoriums He hoped that no hasty step would be taken, for he was convinced that from every point of view it was better to utilize the existing accommodation at any rate for all early cases of the disease Better results would be obtained in properly equipped sanatoriums than could be obtained in a multitude of small ones He was sure it would be cheaper to use and even extend the existing sanatoriums Until quite recently Newcastle Sanatorium had by no means been taxed to the full extent of its resources and he believed that that was true of the other Dublin sanatoriums On the other hand separate provision in each county or in group of counties for advanced cases in which nursing only was required was most desirable Such cases could be looked after more comfortably in hospitals than in the patient home and removal to hospital would lessen infection to others Dr Moorhead referred to the lack of provision for after care Public health officers were encouraging and developing a system of domiciliary visits but a great deal more was required The establishment of a tuberculosis colony at Portrane was an important step and he was glad to learn that the colony was now willing to accept patients from sanatoriums other than Peamount Referring to milk Dr Moorhead said he was still strongly of opinion that a Bill to ensure a clean milk supply was absolutely essential prevention was better than cure and in the long run cheaper He hoped that a Milk Bill would be introduced and carried through all its stages before long

Benn Ulster Hospital

The report presented to the annual meeting of the Benn Ulster Eye Ear and Throat Hospital stated that 950 patients were admitted into the wards during 1931, 6 000 new patients attended the extern department and there were 11 042 attendances of old patients Lieut Col A B Mitchell M D in moving the adoption of the report said that the hospital was founded by Edward Benn in 1871 and had therefore carried on its beneficent work for sixty years The original hospital cost £3 180 and £10 000 had been spent in alterations and extensions during the last fourteen years In 1918 the total attendances were 5 875 last year they were 17 032—an increase of almost three times in the fourteen years He explained the marvels of the construction of the human eye ear and larynx and said that the skill and training of their staff in dealing with these delicate organs and the work done by them could not be surpassed in any similar institution The fame of Dr M Keown still clung to the hospital and the staff to-day maintained and surpassed the best work of Dr M Keown Referring to squint Colonel Mitchell said this condition was now rare because of the excellent work done in institutions such as theirs by skilful correction of squint in childhood It was very interesting to note that their hospital had been in the vanguard in the matter of pay wards and paying patients Abuse of the voluntary system had thus been prevented and their annual income materially increased There must always be however a large number of applicants who were unable to contribute and a generous public had enabled the hospital to deal with these unfortunate people for over sixty years and it would not fail them now The steady increase in the attendances at the hospital was a clear proof of the efficiency of the staff However splendid the building and however modern its equipment nothing but first class work could ensure and maintain its popularity

Monkstown Hospital, County Dublin

Dr Bethel A Solomons Master of the Rotunda presiding at the annual meeting of Monkstown Hospital said that 584 patients had availed themselves of the wards of the hospital during the year, while 2 444 had been treated in the dispensary 4 300 accidents had been attended to in addition to 31 accidents arising from motor cars There had been 148 surgical and 157 dental operations 440 attendances in the x ray department and 1 458 massage treatments The operating theatre, through the generosity of Miss Beatty had been reconstructed redecorated and refitted at a cost of £250 The committee after most careful consideration of the financial position of the hospital felt that notwithstanding the objections which some subscribers might have to sweepstakes it would not be in the interest of the hospital to refrain further from participating in the Irish Hospitals Sweepstakes They had accordingly decided by a majority to fall into line with other hospitals The bank overdraft amounted to £1 272

Free State Vital Statistics

The births registered in the Irish Free State during the quarter ending December 31st 1931 numbered 13 222 a birth rate of 17 9 per 1 000 estimated population This rate is 1 below the average for the fourth quarter of the ten years 1921-30 The death rate was 13 per 1 000 (the total number of deaths being 9 620) while the infant mortality rate was 66 as compared with an average of 70 for the fourth quarter of the preceding ten years The number of deaths from all forms of tuberculosis during the quarter was equivalent to an annual rate for the corresponding quarter of the five years 1926-30 The number of deaths ascribed to accidents and diseases of pregnancy and childbirth was equivalent to 4 2 per 1 000 the rate for the fourth quarter of 1930 being 5 1 The summary of the quarterly returns for the whole year shows that the birth rate was 19 3 per 1 000 population as against 19 8 for 1930 and an average of 20 2 for the ten years 1921-30 The mortality rate of children under 1 year was 68 per 1 000 births as against the previous ten year average of 70 per 1 000

Scotland

Edinburgh Royal Blind Asylum

At the meeting of directors of the Royal Blind Asylum and School Edinburgh Dr George Mackay presented his final report as oculist to the institution and described the measures which had lessened the incidence of blindness and ameliorated the condition of the blind during his term of office He said that he had frequently experienced difficulty in diagnosing accurately the causes of blindness on account of the inadequate and misleading history supplied by the applicants for admission or by their guardians or representatives As far back as 1890 he had urged the desirability of inquiry into the physical condition of every school child including eyes and eyesight but it was not until 1904 that the first systematic examination of the eyesight of school children in Edinburgh was conducted by Dr E M Lithgow at the request of Sir Leslie Mackenzie The eye clinic of the Edinburgh School Board was started in 1912 and the introduction still later of schemes for maternity and child welfare had ensured the early recognition of defective eyesight The latest development was the establishment of clinics under expert ophthalmic surgeons through whose certificates alone the benefits of the Blind Persons Act 1920 could be obtained

If the standard of blindness which was already demanded in Scotland and recommended for adoption in England received international approval the worldwide statistics of blindness would be much more reliable than they had been in the past The chairman Dr Thomas Burns said that Dr Mackay had been oculist to the school for thirty-one years his services had brought great credit to the institution and he would continue to be its honorary consulting ophthalmic surgeon

Finlayson Memorial Lecture

The memorial lecture which was recently instituted at the Royal Faculty of Physicians and Surgeons Glasgow was delivered on April 21st by Sir D'Arcy Power F.R.C.S. who took as his subject The progress of surgery at St Bartholomew's London Hospital 1880 to 1940 Dr R Barclay Russ President of the Faculty occupied the chair The lecturer said that he felt his subject would have met with the approval of Dr James Finlayson who was born in Glasgow in 1840 and died in 1906 after having been for more than a quarter of a century librarian to the Faculty and physician to the Western Infirmary During the half-century in which the speaker had been attached to St Bartholomew's Hospital there had been revolutionary changes At the beginning of this period the surgeons lived in what might be called water-tight compartments meeting at weekly consultations but rarely entering each others wards and never visiting foreign clinics It was not surprising therefore that these surgeons at St Bartholomew's failed to understand the significance of the revolutionary changes which were being brought about by Lister and his pupils They were satisfied with their results for they were not accustomed to travel more than a few miles from London and they were without the scientific education which would have enabled them to understand the principles governing the practice of antisepsis The history of operations during this half-century had been one of battles brought to an issue mainly by the method of trial and error especially in connexion with hernia cancer of the breast cancer of the tongue and appendicitis The changes had largely been effected in the present generation following the sound biological training of medical students of the previous generation under Huxley Ilelleston and Ray Lankester

Social Services in Glasgow

Dr A K Chalmers late M.O.H. for Glasgow in the course of a recent lecture to the City of Glasgow Society of Social Service dealt with the requirements of a complete scheme of medical service and the relation of the family doctor to such a scheme He said that the school medical service was the only service which had admitted supervision of the health of individuals over a prolonged period This service accordingly presented a more complete picture of effective provision than existed elsewhere among the civilian population The subject had recently been approached from a new angle for a committee consisting of representatives of the British Hospitals Association and of the British Medical Association had considered and reported upon the subject of institutional treatment This committee stated that institutional treatment should largely displace treatment in the patients own home and that it was likely to increase in the future The lecturer believed that the National Health Insurance Act was having a child and ten for more efficient health service in the future In the present state of medical practice it was estimated that 80 per cent of the Glasgow population were ill without asking for help and it was assumed that this would be doubled if [illegible] were extended to [illegible] ant It was claimed that under the operation of the scheme [illegible] attention which [illegible] illness was coming and could be treated at an earlier stage than formerly but the work of the practitioner was now directed towards prevention and there was a more marked recognition of the social responsibility borne by the profession to the community

Glasgow Ear Nose and Throat Hospital

At the annual meeting of the Ear Nose and Throat Hospital of Glasgow held on April 21st Mr G W Service Lord Dean of Guild who presided referred to the great interest in attendance at the hospital and in applications for admission in recent years During the past year the work of the hospital had increased by 10 per cent and the waiting list for some time had averaged over 2 000 The report of the directors showed that during the past year the attendances had been 39 412 an increase of 6 604 over the number for the preceding year The subscriptions had amounted to £1 814 which was £76 less than for 1940 expenditure however had also shown a decrease of £289 so that the loss on the year's working amounted to £784

England and Wales

Bristol Colony for Mental Defectives

Horfield Colony for Mental Defectives eight miles from Bristol was opened by Sir Hilton Young Minister of Health on Friday April 29th This is the first complete colony to be built since the passing of the Mental Deficiency Act in 1913 It is situated about four miles from the northern boundary of the city of Bristol south-east of the Bristol Gloucester road not far from the well known viewpoint of Almondsbury The colony which is 126 acres in extent was designed by Messrs W S Skerrett and Sons architects to accommodate some 600 inmates with room for extension for about 1 000 It comprises ten homes for the patients a low-grade ward workshop laundry school hospital nurses home and administration block The Lord Mayor of Bristol (Mr John Inskip) presided at the opening ceremony at which some 500 people attended and in his speech congratulated Alderman Ernest Sheppard (chairman) and the Bristol Mental Deficiency Act Committee upon seeing the completion of the work to which they had devoted so many years of effort The Minister of Health also paid tribute to Mr Sheppard saying that it must be a proud day for Alderman Sheppard and his committee to have built and equipped the first complete colony of this kind for dealing with one of the most tragic and most difficult social problems of the day He also referred to the question of [illegible] mental defectives and recalled that [illegible] upon a preliminary investigation by experts of the [illegible] of these children [illegible] He said that he would hereby [illegible] letter and the [illegible] tion

An Anti-Cancer League

The [illegible] West Middlesex [illegible] and treatment [illegible] open [illegible] of [illegible] [illegible] [illegible]

evidence it has received of the necessity for early diagnosis if the best results in the treatment of malignant disease are to be obtained. The danger of making people morbidly over-anxious about cancer is appreciated, but it is believed by those initiating the movement that if the propaganda is undertaken in the right way and it is brought home that early cancer is curable it will have in general the opposite effect, relieving large number of middle-aged or elderly people from the secret unuttered fears and foreboding which now plague them.

Wimbledon has been made the starting point of the campaign and on April 27th at a public meeting in the town hall there over which the mayor presided and which was largely organised by the vicar the Rev. Clarence Hamilton what is to be known as the Mount Vernon Anti-Cancer Education League was inaugurated. In this League members men and women over 40 will promise that however healthy they may be feeling they will visit the doctor for overhaul every six months and will encourage others to do the same. A message was read from the King who is patron of the Mount Vernon Hospital expressing his interest on learning that the campaign was being inaugurated in the royal borough and his best wishes for its success.

An address was given by Dr. Malcolm Donaldson who is acting secretary to the advisory committee at Mount Vernon which is concerned with the matter. Dr. Donaldson stated that it was now beyond question that cancer could be successfully treated if detected at an early stage. The main reason for failure to see a doctor at that stage was the common belief that a swelling did not cause pain it could not be cancer whereas in fact early cancer was in many cases painless. As it was impossible to teach people themselves the detection of the early signs the only practical method appeared to be regular visits to the practitioner. The records of the Ministry of Health regarding cancer of the female breast said Dr. Donaldson showed that only about half the patients sought advice and treatment while the disease was at a curable stage. He dealt briefly with the modern treatment of cancer by radium x rays and operative procedure and with the work at present being done on cancer in the direction of discovery of the cause of the best form of treatment and of the most certain means of early recognition. He also gave examples of various forms of cancer attributable to long-continued irritation such as cancer of the tongue due to a jagged tooth. The well-known film by Dr. R. G. Canti illustrating the division and multiplication of cancer and other cells and the effect of radium upon them was also exhibited. A pamphlet was issued at the meeting bearing the title "Early cancer can be cured" together with a reminding card. It is the policy of the campaign to form as many branches of the League as possible the ideal being to have one in every town.

In a letter addressed to members of the medical profession asking for their co-operation, the authorities of Mount Vernon suggest that for the present the people who are likely to come forward for such examinations will belong to the better-to-do classes. When the movement has spread, as it is hoped that it will to the insured population and their dependants it will be time to consider the question of the best arrangement from the busy practitioner's point of view, for these periodical visitations, and of his remuneration.

Value of Hospital Almoners

With a view to interesting those responsible for the administration of hospitals both public and voluntary in the work of trained almoners, a meeting of hospital representatives was held recently at the Medical Institution Liverpool by invitation of the local training and advisory committee of the Institute of Hospital Almoners the medical officer of health presiding. Dr. R. C. Wingfield, medical director of the Brompton Hospital Sanatorium at Frimley said that though the hospitals, through their out-patient departments, seemed gradually to be taking over much of the work formerly done by the general practitioner it was vitally important that a link with the homes of the patients should be maintained and this could only be secured through the co-operation of an efficient almoner. Miss Macintyre assistant almoner at St. Thomas's Hospital, London discussing some of the functions of the hospital social service worker mentioned particularly her opportunities for preventing the waste of skill and effort of medical men by means of efficient following up of cases discharged from hospital and the utilization of auxiliary social services. By means of expert and kindly inquiry the abuse of hospital resources might be prevented.

King's College Hambleden Department of Anatomy

The Hambleden Department of Anatomy at King's College London which was the subject of a descriptive article in our issue of April 16th (p. 720) was opened on April 27th by the Earl of Athlone, the new Chancellor of the University of London. The Principal of King's College (Dr. W. R. Halliday) said that the ceremony marked the completion of the first stage in the reconstruction of the College to meet the requirements of modern scientific education. The department also represented the College memorial to the second Viscount Hambleden, to whom King's owed more than to any other individual. The generosity of the London County Council to the University had now enabled the Court to make a substantial capital grant (£35,000) to the cost of the Hambleden Department and the completion of the first half of the building scheme. From the Centenary Appeal Fund a sum of £25,000 had been drawn and the remainder of the expenditure on the building was being met from savings made for the purpose. The Earl of Athlone in opening the department said that the department would stand as a witness of how closely interwoven were the schools of the University. Here the students of to-day who would be the doctors of the morrow received their pre-clinical training before passing on to one of the medical schools of the University. These important ties were further strengthened when clinicians from the associated hospital medical schools—Charing Cross St. George's Westminster and King's College Hospital—accepted honorary teaching posts in the medical department of the College, and when College professors responded to cordial invitations to give of their knowledge to the hospital medical schools. He recalled that King's College Hospital was founded by the medical faculty of the College. In 1910 the hospital medical school and the College medical faculty separated amicably the College becoming pre-clinical only while the hospital, now on Denmark Hill was clinical and clinical only. The College then linked itself up with other medical schools and in step with Oxford and Cambridge prepared students up to a point which, he believed was the second examination for the medical degree, and after which they moved on to one of the hospital medical schools for their clinical instruction. The Chancellor concluded with a reference to the late Lord Hambleden saying that he cherished the recollection of working for many years with him on the British Hospitals Association. Professor Duncan M. Blair in proposing a vote of thanks to the Chancellor, said that the opening of this new department was not only a College affair but also a University affair because the medical faculty at King's was a centre of university medical education which worked in conjunction with

the clinical schools of several London teaching hospitals The new department would enable them to play their part in that team with greater efficiency It would certainly be their earnest endeavour to promote still further co operation with the clinicians in the hospital schools in working together on the great problems of common interest In the new department there would be greatly increased research facilities which allowed that co operation with the clinicians to be more extended than had been possible in the past In addition new facilities for microscopical work (which even apart from the normal teaching of histology was an essential part of the modern teaching of anatomy) would be available and it was hoped to prosecute with greater efficiency than had been possible in the past the work in developmental anatomy and neurology which he believed were the most vital branches of anatomy to day The resolution was seconded by Dr E Barclay Smith professor emeritus of anatomy who recalled the fact that the department was originally established in dungeons at the south eastern corner of the building At that time the professor of anatomy was concerned not only with the study of the form but of the function The study of function however soon demanded special treatment staff and equipment and therefore a separate department of physiology was created and he believed that King's College was the first institution in this country to appoint an independent professor of physiology For years the two departments worked side by side in the greatest harmony but the time came when the younger department found increased accommodation in another part of the College and now at length anatomy had followed its example and the two departments were once again topographically and in other respects closely linked together

ADVERTISING AND CANVASSING

SIR —The attention of the General Medical Council has been called to a proposal to provide free medical attendance for purchasers of a commodity which is to be sold through the agency of advertisement and canvassers I am directed to point out that any registered medical practitioner who associated himself with such a scheme might be held to have contravened the Council's Warning Notice in regard to advertising and canvassing and to have rendered himself liable to be summoned to appear before the Council in answer to a charge which if proved might have serious consequences The warning referred to above is as follows

> The practices by a registered medical practitioner
>
> (*a*) of advertising whether directly or indirectly for the purpose of obtaining patients or promoting his own professional advantage or for any such purpose of procuring or sanctioning or acquiescing in the publication of notices commending or directing attention to the practitioner's professional skill knowledge services or qualifications or depreciating those of others or of being associated with or employed by those who procure or sanction such advertising or publication and
>
> (*b*) of canvassing or employing any agent or canvasser for the purpose of obtaining patients or of sanctioning or of being associated with or employed by those who sanction such employment

are in the opinion of the Council contrary to the public interest and discreditable to the profession of medicine and any registered medical practitioner who resorts to any such practice renders himself liable on proof of the facts to have his name erased from the *Medical Register*

—I am etc

LACTIC ACID IN THE GASTRIC CONTENTS

SIR —During the past five years Dr Alexander Calder and I have made bacteriological and biochemical investigations of the gastric contents of approximately 100 cases of cancer of the stomach During the same period several hundred patients suffering from other diseases were similarly examined A paper dealing with these investigations will appear in the near future but on account of the present interest in the subject I wish in this brief communication to state that in our experience lactic acid is commonly found in cases of cancer of the stomach but is rarely detectable by the ferric chloride or thiophene tests in any other condition In short our experience agrees with that of Dr F Craven Moore (*Journal* April 23rd) and is completely at variance with the figures reported by Drs Murray and Robertson (*Journal* April 2nd)

The quantitative methods employed by Dodds and Robertson for the estimation of lactic acid in gastric juice are capable of demonstrating amounts of lactic acid which are so small that negative results are obtained with the usual clinical tests From a practical point of view it is not of much importance whether such traces of lactic acid are or are not present in normal gastric juice It would however be of real value in diagnosis if it could be shown that a positive ferric chloride or thiophene test occurs more frequently in cancer of the stomach than in any other gastric condition This I believe to be the case although it must be clearly understood that the presence of lactic acid is in no way pathognomonic of gastric cancer since it undoubtedly occurs in other diseases both intra and extra gastric The factors which favour the production of lactic acid are however more frequently present in gastric cancer than in any other type of gastric disease Quantitative methods for detecting lactic acid are too complicated to become routine clinical procedures while the ferric chloride and the thiophene tests have certain disadvantages which if not fully appreciated will lead to erroneous results

Without going into details at present I suggest that the contradictory reports appearing in the literature recently can be explained on this basis —I am etc

Aberdeen April 26th

MALIGNANT DISEASE OF PHARYNX AND LARYNX

SIR —I was very pleased indeed to read in the *Journal* of April 30th Mr F Muecke's straight out opinion upon the treatment of cancer of the pharynx and larynx I agree entirely with what he says

It is now more than ten years since first I practised and began to preach the complete removal of pharyngeal cancer when it is eradicable by the diathermy knife coupled with the clearance of the cervical gland area from the same side of the neck A small number of colleagues have like Mr Muecke followed the same plan and I am sure I express their opinion as well as my own when I say that the operation has proved to be as satisfactory as one can expect in so deadly a form of cancer But the operation is severe and necessitates a special technique and knowledge Partly for that reason but also no doubt as a result of the recent radium furore it has been to a great extent supplanted by the insertion for prolonged periods of radium tubes even unfortunately in easily eradicable growths On the whole results have not been good yet the practice continues Not to go deeply into the subject but to mention only one point—the most obvious and certain of the sequels of the lengthy lodgement of a foreign body in the malignant area communicating with the septic cavity of the mouth—I may say that severe septic infection is a frequent result

and we find the misery of this most distressing form of cancer intensified by the addition of sepsis not only local but general

On the other hand diathermy even in incurable cases is often useful for when properly used it may be a most merciful remedy I have at this moment, for example two patients under my care both with incurable cancer In one an epithelioma involves the posterior surface of the soft palate and the lateral walls of the nasopharynx When he came he was suffering the acme of incessant facial neuralgia from involvement of branches of the trigeminal in the growth He has been diathermised on several occasions and he has been free from neuralgia since the first The man is able now to talk without tin to his friend The second case is that of an epithelioma of the chief and maxillary antrum Diathermy has also kept this patient active and free from pain for the last six month

So much for hopeless cases As to the results of diathermy excision I have case on my list of three five and even ten years freedom from recurrence Such results in a malignant form of the disease are sufficient evidence only of the value of this method of treatment and I can heartily support Mr Mueller in once more commending it to the notice of laryngologists —I am etc

DE MCKENZIE

POLYCYTHAEMIA RUBRA AND ACHLORHYDRIA

SIR —Dr Robert Platt in recording his case of polycythaemia rubra vera apparently overlooked the cases reported by Minot and Buchman's paper appeared in 1927 and Osgood Castleman and Drobey's described two cases in 1928 (*Amer Journ Med Sci* 1928 clxv 257) and in 1930 I recorded the first in this country (*Lancet* 1930 i 1129) Of the five cases which have come to necropsy two were found to have an aplastic bone marrow and in both were complicated by syphilis it was my belief that antisyphilitic measures had been the cause of the anaemia Irani (*Schittenhelm's Krankheiten des Blutes* Berlin 1925 ii 111) has shown that salvarsan can produce an aplastic marrow

Dr Platt's case is of special interest in that antisyphilitic measures did not retard improvement and in that—as in the case I recorded—there was chronic glossitis and improvement on liver diet No fractional test meal was carried out in my case and in spite of improvement in the blood condition he died of an intercurrent polyserositis —I am etc

HAROLD AYERS

London W 1 April 27th

ANATOMY AND SURGERY

SIR —The anatomy of the textbooks is admirably suited to the aims of examinations as a memory test it is only excelled by certain of the Chinese classics But the surgeon who turns to these books for a description of the living human body that can help him in his craft finds them (to quote from an early report on the island of Ceylon) replete with innumerable abominations I agree with the reviewer (in the *British Medical Journal* of April 30th) that *Cunningham's Anatomy* (sixth edition) stands second to none of its kind and for that very reason I think that criticism from the surgeon's point of view may be of interest This criticism after an attempt to supplement my scanty understanding of certain regions I would arrange under three main heads

1 A fact of interest in the mechanics of the body which is perhaps only to be expected from those whose work is on the cadaver For example

(*a*) The method of closure of the nasopharynx in speech and swallowing is vaguely and inaccurately described The important point that the tensors and levators of the palate act in opposition is not mentioned Passavant's ridge[1] is described is being opposite the body of the second cervical vertebra whereas it actually is just below the adenoid bed (The adenoids end at the foramen magnum not at the arch of the atlas) Naturally when the ridge is wrongly placed it is not recognized that it is the posterior half of a sphincter whose anterior half is the soft palate though this is obvious enough in a gagging patient

(*b*) The mechanism by which the tonsils however prominent are prevented from descending with the bolus as it is swallowed is not described

(*c*) In discussing the inguinal canal no mention is made of the essential fact that the contraction of the abdominal muscles which is the only force that can drive the abdominal contents through it automatically closes it[2]

(*d*) No mention is made of the definite and important band of fibres which Hesselbach called the internal crus of the internal inguinal ring[3]

(*e*) No mention is made of the secondary fibrous suspension of the testis which takes its weight when the muscles relax This band runs up with the spermatic vessels and spreads on their outer side into the extraperitoneal tissue over the iliacus The structure most resembling it in the books is the internal spermatic fascia which as a funnel shaped investment for the cord from the transversalis fascia I have yet to see dissected out

2 An unfamiliarity with structures which are not well developed in the aged derelicts who come to the dissecting tables though these structures may be of importance earlier in life For example

(*a*) *The tonsil* I am pleased to observe the dawn of doubt regarding the classical description which makes half a dozen arteries concentrate on this anaemic lump of lymphoid tissue[4] There is of course only one and it might be as well to indicate its very constant place of entry Persistent post operative haemorrhage is still described in terms of arteries though to a general surgeon it is obviously venous and the vein that causes it is not described[5] There is no supratonsillar fossa[6] and the hole in the substance of the tonsil which the anatomists persist in calling by this name is very unlike the plan of it in Fig 869

(*b*) *The adenoids* In contrast to the misdescription of the tonsils these are to all intents not described at all It is a solemn thought that though any student would resent as unfair a question about the relations of these large and extremely interesting structures they and the tonsils are the organs which he will most confidently attack on graduation The horrors preached and practised in the surgery of the throat can only be explained by ignorance of anatomy I and I can only be explained by ignorance of anatomy

(*c*) Certain anatomical points in the condition of hypertrophic pyloric stenosis might be mentioned for their surgical importance I admit the wish is egotistical and that the subject borders on pathology[7]

(*d*) There is no description of the lines of junction of the elements of the upper lip though perhaps this is preferable to the usual figure which shows them descending vertically from either nostril The real line of junction can be seen on the mucosa of the undersurface of any baby's lip[8 9]

3 A most confused description of the fibrous tissue of the body This is probably due to that matting of the layers of the cadaver which is produced by preservative and which lends such a sporting interest to examinations in operative surgery For example

(*a*) The classical transversalis fascia continuous above with the renal fascia and inserted below into the crest of the ilium is an anatomical Mrs Harris whose origin is a confusion between the extraperitoneal connective tissue and the aponeurosis of the transversalis muscle I think I can discern the onset of suspicion here too but what is wanted is a categorical statement that the fibrous layer of the peritoneum

[1] Stein *Wien med Woch* 1930 lxxx 1152
[2] Symington *British Medical Journal* 1910 ii 1353
[3] Russell Hamilton *Lancet* 1899 ii 1416
[4] Hesselbach *De Ortu Hernarum* 1816
[5] Browne *Journ Anat* 1928 lxii 82
[6] Hett and Butterfield *Journ Anat and Physiol* 1904 xlv 35
[7] Browne *Arch Dis Child* 1931 vi 129
[8] Retzius Gustav *Biol Untersuchungen* 1 ol xi Pl xvi
[9] Veau *Ann Anat Med Chir* 1926 v 601

the extraperitoneal connective tissue the tela subserosa the transversalis fascia the iliac fascia the renal fascia the visceral layer of the pelvic fascia etc are all the same continuous layer and can only be intelligibly described as such It should be possible in this description to score a point against the surgeons by pointing out that their extraperitoneal approach to the ureter is outside this layer and leads into the cave of Retzius in one direction and behind the kidney in the other

(*b*) The pelvic fascia that mystery which has reduced so many students to a becoming state of modesty by defying them to understand it is a mare's nest It is constructed by the strange device of calling the aponeuroses and tendons of the pelvic muscles its parietal layer and the packing material round the viscera its visceral layer though these two tissues differ developmentally functionally and structurally Cunningham's account of it is the most rational I have seen but the confusion will remain till the word fascia is entirely dropped Anatomy is one of the exacter departments of medicine and one of the first requisites of exact description is a narrow and sharply defined meaning to all terms used Apart from the pelvic fascia compare the fascia lata which is a tendon and the fascia of Camper which is a vague concentration of fibrous tissue Or note that the tendinous expansion of the palmaris longus is an aponeurosis while the precisely similar expansion of the hamstrings is fascia

—I am etc,

London W 1 May 2nd DENIS BROWNE

TREATMENT OF OSTEO ARTHRITIS OF THE HIP JOINT

SIR —Osteo arthritis of the hip joint has usually been regarded as an incurable and progressive disease I am glad to see that both Dr Hernaman Johnson and Dr Douthwaite take a less sombre view of the condition Dr Hernaman Johnson speaks of great improvement and of non recurrence under deep *x* rays in doses not large enough to upset the patient constitutionally Dr Douthwaite claims that the vast majority of patients can be relieved of pain and of much disability by partial or complete restoration of movement by manipulation and the use of a walking calliper He is not so convinced of the value of *x* rays and only has recourse to these if after manipulation pain persists In fact Dr Douthwaite rather goes out of his way to make the point that after *x* rays lasting improvement only occurs in the minority of patients

Whatever the cause of this difference of opinion—and perhaps it is only a matter of dosage—are not both Dr Hernaman Johnson and Dr Douthwaite erring somewhat on the side of optimism? One would like to have something definite in the way of evidence Do radiograms taken a year or two after these methods have been employed show that the disease has not progressed? If manipulation is so successful surely the unqualified practitioner would have reaped a wonderful harvest yet patients commonly state that they have been told by an osteopath that they have arthritis and must consult a doctor for he the osteopath can do nothing for them

The matter is of great importance and the opinion of others who have made a special study of the condition would be valuable What have our orthopaedic surgeons to say in regard to the end results of deep *x* ray therapy and of manipulation? In your last issue Mr Whitchurch Howell at any rate expresses himself in no uncertain terms There are now quite a number of medical men in London who have studied and practise with success methods learnt in the osteopathic colleges of America and elsewhere What is their opinion of the end results in osteo arthritis of the hip? Will not general practitioners who collectively must have the biggest experience of all tell us what they find? The Rheumatism Research Committee of the British Medical Association might with advantage take up the point in any collective investigation which it may be contemplating

Osteo arthritis of the hip joint is a most distressing and disabling disease With all diffidence I would like to suggest that it can seldom be treated successfully by any one method alone but that none the less the problem is a fairly straightforward one since constitutional symptoms are absent and attention can be concentrated on the joint alone

My own experience is that cases must be divided into active and inactive The former comprise those where inflammatory changes predominate and bone change is slight *X* rays usually show hazy outlines and generally some cystic formation is visible The symptoms are severe The inactive type shows more bone change limitation of movement is a feature but pain mostly occurs on walking and rest is not disturbed In the active type manipulation I would suggest is always wrong and deep *x* ray therapy in anything like massive doses may be followed by intense and lasting reaction In every case there is some risk of lighting up the disease by manipulation but far more so in the active case For the walking calliper I fear I have no good word Muscular atrophy such a feature of the disease is always aggravated by its use nor must it be forgotten that the disease is rarely confined to one hip joint

I would like to advance the view that osteo arthritis of the hip is an infective condition of great chronicity and I would suggest that the cystic condition so often seen and incidentally mentioned in your last issue by Dr Matthew Ray is evidence of this for as I have shown these rarefied areas can be reproduced in rabbits at will by the intravenous injection of certain streptococci From these areas which show all the appearances of a localized infection the same streptococci can be recovered If I am right the most hopeful line of attack would appear to be a preliminary course of vaccines accompanied by subsidiary measures to recondition the muscles and gentle stretching to maintain the fullest possible range of movement followed later by deep *x* rays which certainly do help to increase the range of movement and to reduce pain by manipulation and in some cases of marked contracture or intractable pain by operative measures

X rays taken at intervals of a year or two show that vaccines do in fact tend to check the disease Bony change does not increase and hazy outlines clear up Space does not permit any consideration of the details of the vaccine to be used but the patient will be overhauled for foci and pathogen selective culture should not be omitted —I am etc

London W 1 May 2nd H WARREN CROWE

SIR —In your issue of April 23rd there appeared two letters one from a physician and one from a radiologist testifying to the value of *x* rays in osteo arthritis With Dr Kempster's letter I am naturally in entire agreement I note that Dr Douthwaite refers to pain only He does not tell us about the walking or working capacity of these patients before and after treatment This is a matter which from an economic point of view is even more important than the question of pain

I have collected a considerable number of these cases and have recorded their initial condition and their progress according to a simple but practical system On each patient's card is noted in addition to the history (1) walking capacity (2) working capacity (3) pain at night and (4) pain in day The following is the record of a case chosen not because it is exceptional but because the patient was shown before a Divisional meet-

ing of the British Medical Association and will doubtless be remembered by some of your readers

A married woman aged 62 had had pain in both hips since 1911 A radiograph here discloses deformity of both femoral heads and of the acetabulum with abundant osteophyte and destruction of the intra-articular cartilage

She was last seen on November 26th 1930 when the following notes were made *Walks, abducts* well with great difficulty with aid of two sticks and for a few hundred yards only *Rotates, all hips* well *Lies at rest* unable to lie except in middle and on back only *Pain in day time* pain in day time Pain comes on after walking

Sixteen months later April 11th 1932 the following observations were made *Walks* abducts short distance without pain Up to three miles with one stick *Rotates, abducts* able to do the necessary duties of own allotment *Lies* no pain night or day

The radiographic picture does not seem to change but I have not noticed that a crippled patient who has been enabled to walk freely do a full day's work and enjoy freedom from pain is greatly troubled by this fact It cannot rightly be expected on *a priori* grounds that osteophyte would be absorbed or a destroyed intra-articular cartilage be reformed All one can hope for is that the activity of the disease process be arrested Nature will make the best of a bad job within the well known limits of her capabilities

Dr Douthwaite recommends restoration of movement by manipulation and the use of a walking calliper But surely if the capacity of x rays to improve function as well as to relieve pain is once established the agents should be used *in conjunction* with the above measures Here is an obvious opportunity for combined treatment The special plea in my former letter was however that cases should be diagnosed and treated before there is appreciable limitation of movement —I am etc

London W 1 April 27th J HERBERT JOHNSON

THYROID EXTRACT AND PULMONARY EMBOLUS

SIR,—With regard to the memorandum by Mr Fraser and the letter by Mr Hannan on this subject appearing in your issues of April 9th and 23rd respectively surely it is not reasonable to expect any marked prophylactic effect from thyroid which has only been administered over a period of about a fortnight Anyone who has treated a case of hypothyroidism with this gland and who has carried out determination of the basal metabolic rate by some reliable method such as the Douglas Haldane is familiar with the delay in response He well knows that no appreciable increase *in rate* ever occurs in less than a fortnight and that even then it is generally slight

It seems to me that if this method is to be of any value the treatment must be instituted at least three weeks before the operation is to take place —I am etc

RICKETS AND VITAMIN D

SIR,—Referring to the letter of Dr Chalmers Watson in your issue of April 23rd I can recall a case of twin sisters who came under my notice in 1909 when I was serving as school medical inspector under the Education Authority in the Midlands One of the twins had the classical symptoms of rickets to a marked degree while the other presented no signs whatever of the disease Both children had been brought up on the same diet At this distance of time I cannot recall details but the circumstance made a vivid impression on my memory and I have since regretted not having drawn attention to it at the time —I am etc

London April 30th EVA MCCALL

ALUMINIUM AND HEALTH

SIR,—May I briefly refer to your comments on my monograph in your issue of March 26th? A possible explanation of the apparent non toxicity of aluminium in nature may be that it exists in vegetation in a colloid form but in any case the amount imbibed in this way is infinitesimal compared with that taken in artificially with cooked foods

As to no occupational disease having hitherto been attributed to aluminium it must be borne in mind that no disease or ill health of any kind in any class of life has previously been attributed to this cause The insidious nature of the symptoms and their unsuspected origin sufficiently account for their being overlooked I would not expect any crude symptoms from imbibed particles for these would not be rendered soluble in the lungs as they are in the stomach Any aluminium dust swallowed in the course of work would be but a trifling addition to that taken daily *in food*

The use of alum for cleansing water will need the gravest consideration in the future as has been pointed out to me by the *Director of Hygiene* of the War Office Our own and many foreign Governments recognize the poisonous effect of alum and forbid its use in baking powders this being at least one instance of divergence from the concordance of expert opinion to which you refer

Negative deductions on healthy young men are worthless for their systems having been actively throwing off this metal in increasing amount since birth can readily reject an additional quantity without apparent ill effects It is a significant fact that it is medical men getting on in years who write thanking me for their recovery from prolonged ill health since stopping aluminium cooking The incredulity of those who have not personally experienced the ill effects of this metal on their own bodies is natural especially when supported by apparently authoritative opinions emanating from America and Germany But these are based on laboratory work and the fact that animal experiments in one country under certain conditions are negative does not disprove positive findings in other countries under other conditions The former may be genuine but the fact that opprobrium alone rewards the latter tends to give their results greater credence

If at any time under any conditions lesions or deranged health have been produced in animals by aluminium salts it is obvious that we must remove all possibility of such a risk to human beings But after all this is a human question, so why waste further time over animal

experiments from the other side of the globe when we have only to step outside our own doors to find abundant first hand proof in our fellow men? The fact that toxic effects can be produced if large quantities of aluminium compounds are given as you say justifies us in taking every possible measure to save humanity from the extreme danger of continually taking in these substances in ever increasing quantities as at present—I am etc

AETIOLOGY OF CANCER

SIR—Dr Gye in the *Journal* of April 9th uses an expression which may be expected to arouse controversy Such a statement as the obvious conclusion the only conclusion may be applicable to a mathematical proposition if all of the facts are known but the established facts given by Dr Gye are not the only facts and therefore his conclusion may not be the only conclusion There are certain things which have been left out and the conclusion to be derived from these may be that the changes are not so much those to which the word immunity as generally understood can be applied as that an alteration has taken place in the physiological balance of the animal

Dr Gye writes that the tumour in the duck always recedes So there is something in the duck which prevents the growth of this tumour and this something might be an immune body or the natural physiological effect of injecting a foreign body But if normal mouse tissue such as spleen liver testis or other normal tissues and certain substances such as olive oil be injected into a normal mouse it will be found impossible to get cancer to grow in that mouse This cannot be ascribed to an immunity produced by or to an organism A conclusion to be derived from these facts is that the results can have nothing to do with a virus which is diametrically opposite to the conclusion drawn by Dr Gye—I am etc

Harrow April 30th

BRONCHOMONILIASIS IN JERSEY

SIR—In a recent paper (*British Medical Journal* April 2nd) Dr F H Young has described a condition of chronic bronchial catarrh which commences in early childhood and which persists through adolescence into adult life To recapitulate the condition which is a recognized clinical entity has been described as commencing with an attack of whooping cough or measles Chronic cough and dyspnoea remain there are acute attacks of bronchitis of a fine type which tend to recur with increasing frequency until suspicion of tuberculosis is aroused Such is the typical case history The aetiology is somewhat obscure Adenoids rickets Pfeiffer's bacillus or an unresolved pneumonia have been cited as causes or as contributory factors The treatment is equally unsatisfactory and briefly may be said to consist of hygienic measures and such alterations in the patient's mode of life as will guard against too frequent recurrence of acute attacks of bronchitis There is good evidence that the condition is widespread and that great numbers are crippled by it at an early age I therefore venture to give a short account of work which has been carried out in Jersey during the past ten years believing that we have thrown much light upon this condition as regards both its cause and its treatment

Although it is unusual for a child below 7 years of age to expectorate bronchial secretion we have as a rule succeeded in securing specimens by means of expectorants or by administering emetic dose of ipecacuanha The sputa have been examined direct and by culture and in the great majority the fungus monilia has been found to be present For the past ten years sputa have been examined in this way in addition to the routine examination for tubercle bacilli and cellular content As a result of these findings treatment has been directed against the monilia by means of vaccine and by the exhibition of potassium iodide in full doses by the mouth

In Dr F H Young's paper it is recorded that the sufferers are drawn from the poorer classes for the most part Treatment as we have found to be successful must be long continued From three to five months is a usual course and the drug used in such large doses is costly This has led to the formation of a clinic where suitable cases receive free treatment and medicine The clinic has been established some eighteen months and during that period 120 individuals have been treated with most striking success May I give a typical case history?

A girl aged 9 years Measles three years ago has never been well since Whooping cough nine months ago She is a thin fair child with paroxysmal cough and sputum limbs puny tires very easily teeth and throat healthy slightly furred tongue Dyspnoeic on exertion Monilia cultured from the sputum The chest is well shaped but moves defectively on the left side in its lower half Signs of coarse bronchitis at the angle of left scapula Weight on May 28th 1928 46 lb Potassium iodide 20 grains three times a day given by mouth and vaccine at weekly intervals Weight on August 4th 1928 49 lb Iodide was continued until March 1929 when she weighed 53 lb This child has had no further bronchitis remaining free from cough in both winter and summer alike She attends school regularly and is in all respects normal

We conclude that this condition is one of chronic bronchomoniliasis and that it is relieved by systematic prolonged treatment by vaccine and full doses of potassium iodide Since we have discovered monilia in cow's milk it is considered advisable to sterilize all milk by boiling or pasteurization before its consumption We have noted an increase in these cases during the summer —that is about the time of the calving of cows These observations may have a direct bearing on the causation of June epidemic pneumonia

At a later period in life we frequently find monilia along with the tubercle bacillus in the sputa of cases of pulmonary tuberculosis It would seem to be a fair deduction that moniliasis precedes the infection by the tubercle bacillus and is thus a pre tuberculous condition We are strongly of the opinion that all children who are chronic bronchitics should be subjected to a searching along with the tubercle bacillus in the sputa of cases potassium iodide should be administered in large doses and careful watch should be kept on the body weight and on the physical signs in the lungs—I am etc

H GORDON OLIVER M B B Ch

St Peter's Jersey April 22nd

TREATMENT OF TETANUS

SIR—I have read with interest Dr Leslie Cole's article on the treatment of tetanus in the *Journal* of April 23rd I would however like to include the use of magnesium sulphate as a most valuable method of reducing the spasms This drug which was introduced into the treatment of tetanus by Meltzer and Auer[1] may be given subcutaneously intramuscularly intravenously or intrathecally Intravenously its effect on the spasms is almost dramatic and it is therefore probably the method of choice in an urgent case By this route a 3 per cent solution is given very slowly (about 5 c cm per minute) until relaxation is obtained In a severe case the spasms may return in about four hours and need a further injection Intrathecal injection takes about half an hour to show any result but the effect is much more prolonged Meltzer advises 25 per cent magnesium

[1] Meltzer and Auer *Journ Exper Med* 1906 iv 602

sulphate and a dose of 1 c.cm. per 10 kilograms of body weight or 0.5 c.cm. per 10 kilograms in a child. If any respiratory distress follows the use of magnesium sulphate an intravenous injection of calcium chloride (0.02 per cent. solution) gives immediate relief as it directly neutralizes its action.

The use of magnesium sulphate, of course, in no way replaces the treatment by antitoxin or carbolic acid but is merely an effective measure to reduce the severe spasms without the dangers of repeated chloroform anæsthesia and to tide the patient over until the effect of antitoxin is seen.—I am, etc.

Edinburgh, April 27th.

PREPARATION FOR MARRIAGE

SIR,—I have been reading with great interest and some apprehension of the proposed activities of the British Social Hygiene Council in the matter of preparation for marriage. That those about to marry need some real instruction in matters relating to sex they are in many or most cases taking in with lighthearted appalling ignorance of its seriousness from a physiological and psychological standpoint there is not a shadow of doubt.

Those of us who so often see as I do the unhappy results of this ignorance is exhibited by anxiety states and symptoms in various forms and in not a few cases gross disorder—ending too often in more or less complete functional disorder physiological and psychological very frequently as a consequence in more or less complete disruption of once happy relationships—have for long enough felt the need of some sound pre-nuptial instruction. The only satisfaction left to us at present is that of seeing such persons under suitable advice and management restored to health and happiness (which need never have been lost), when they have been advised to seek such assistance soon enough.

The B.S.H.C. is then absolutely on right lines in making an effort to supply to those about to marry the advice they sorely need. It is however in respect of the proposed manner of imparting this advice that I am apprehensive. If it is to bear good fruit the advice should be within the reach *of every couple contemplating* early marriage and it must be given with the greatest possible care by *thoroughly capable and responsible instructors*. So far I have not seen any mention *of how* the B.S.H.C. proposes to draw up its list of competent advisors (or has already selected them) *which it proposes* to publish (or has published) and place in the hands of persons applying to its bureau for assistance nor have I yet had the opportunity of seeing such list. It would seem however that the general practitioner is not to be considered a competent authority in these matters. Granted that this may be so and in far too many cases is so. It seems to me also the case that a considerable number of gynæcologists neurologists and psychiatrists and a still larger number of general physicians have had equally little or no experience of the duties that the B.S.H.C. is proposing to entrust them with. While I am aware that the *average* general practitioner has not hitherto given these matters the attention they deserve I doubt whether he has given them less attention than has the *average* specialist in those branches of medicine above indicated and I suggest that it is to the general *practitioner* and not to the specialist that the public should be taught to look for competent advice in these *matters*.

It seems to me that the plan adopted by the B.S.H.C. (or about to be adopted) in its splendid effort to bring so greatly needed a service within the reach of the public has been rather ill considered in the best interests both of those it wishes to serve and of the general *practitioner*. The advice needed is of an intimate personal nature and surely it is first of all to the family doctor—who is usually not only that but also the family friend—that the seeker after advice should be encouraged to go. He or she does not go to him (or anyone else) as it is merely because he or she has no idea that such advice is needed or would be helpful.

I suggest that the service which the B.S.H.C. has undertaken to provide would be better *provided* (1) If the public were advised of the existence of the bureau and its purpose. (2) If the council provided the general practitioner (not the public) *with literature setting forth* the evils that now result from the ignorance of couples about to marry and asked *him to see such and such a patient* of his who has applied to the bureau for advice and has been referred to him. (3) If the council supplied the general practitioner with a list of specialists in his neighbourhood to whom he could, if he wished (I am quite sure that he would if he thought his patient would be better served by so doing) refer the inquiring person.

By some such method as this the public would be well served the general practitioner would not feel aggrieved by having his patients advised to seek advice other than from him or through him and if not now feeling competent to deal with such cases as would be referred to him he would very soon take steps to make himself so. Though not one of them I submit that the imparting of such advice is pre-eminently work for general practitioners and that the persons needing it should not be referred to a specialist except by *him*.—I am, etc.

J. W. ASTLEY COOPER.

Meldreth, St. George, April 27th.

FOULING OF FOOTWAYS BY DOGS

SIR,—Those whose fortune it is to dwell in Marylebone will be familiar with those printed notices which the public health authority displays from time to time on our lamp posts and on the sand bins in our streets requesting dog owners not to permit their pets to *foul* the pavements. Even in the Harley Street neighbourhood these timely reminders are to be seen *though* one would have thought that surely there could be no need to indicate the rudiments of hygiene or to stress the elementary requirements of public amenity in such a place. Alas! it would be vain to cherish this pious illusion.

On a recent walk from Marylebone Road to Wigmore Street along a hallowed thoroughfare which shall be nameless the writer had to tread delicately between no fewer than forty-three deposits of dog faeces on the pavement. It can hardly be urged in defence of this horrid state of affairs that non-medical residents in the surrounding district choose—in a puckish spirit—to bring their dogs for exercise to the sombre street in question and thus to keep their own side walks sweet and there seems no escape from the unwelcome conclusion that the medical dog is a singularly dirty and *ill trained creature*.

Any dog may be readily trained to use the gutter if his owner will but take the trouble to teach him to do so. Further the horrified observer who frequents the neighbourhood in the early morning or in the twilight will see that the offending animals are almost invariably *on* the lead when they are rendering the pavements unfit to walk on and he will note with surprise that their mistresses and masters are apparently willing *accessories* before the act. The point need not be laboured but may I suggest that the state of the pavements *in front of* our *consulting rooms* is a reproach to us both as medical men and as dog owners. What must our patients feel when primed with counsels of perfection they *step from our* houses *on* to—what has been described by one who signs himself

Obituary

SIR DAVID DRUMMOND M.D., D.C.L.

Consulting Physician Royal Victoria Infirmary, Newcastle-upon-Tyne; Emeritus Professor of Medicine, University of Durham

We have to announce with much regret the death at Newcastle on April 28th of Sir David Drummond, one of the most distinguished physicians in the North of England, who was President of the British Medical Association in 1921–2.

Born in Dublin in December 1852, David Drummond received his early education at private schools in Ireland and England, and studied medicine at Trinity College, Dublin, graduating M.B. and M.Ch. in 1874. He continued his studies for two years at Prague, Vienna, and Strasbourg before proceeding to the M.D. degree. He then settled in Newcastle and was soon appointed assistant physician to the Children's Hospital. In 1878 he was elected to the honorary staff of the Royal Victoria Infirmary as pathologist and assistant physician. He retired from his appointments at the Infirmary in 1912, and in recognition of his long services was made consulting physician and presented with an illuminated address.

For more than fifty years he was closely associated with the University of Durham College of Medicine at Newcastle. He had been lecturer in physiology, in pathology, and in therapeutics, and from 1911 to 1924 was professor of the principles and practice of medicine in succession to Sir George Hare Philipson. He also served with distinction in the offices of Vice-Chancellor of the University and President of the College of Medicine.

Sir David Drummond was a consistent worker for the British Medical Association. After giving four years to the duties of secretaryship he became president of the North of England Branch in 1891–2, an office he held concurrently with the presidency of the Northumberland and Durham Medical Society. At the Annual Meeting of the Association in Birmingham in 1890 he was vice-president of the Section of Medicine, and at the Newcastle meeting in 1893 he gave the Address in Medicine. He had for some years represented the North of England Branch on the Council before he was, by the suffrage of his fellow-members in that Branch, unanimously nominated to preside over the Annual Meeting of the Association at Newcastle in 1921. The success of that meeting owed not a little to the qualities of mind and heart which had raised Professor Drummond as he then was to the position he held.

For his services in the war as physician to the Northumberland War Hospital he was created C.B.E. in 1920, and three years later he received the honour of knighthood. His own University conferred the honorary degree of D.C.L. upon him, and the University of Glasgow that of LL.D. the Royal Academy of Medicine in Ireland made him one of its honorary Fellows. He had also been president of the Association of Physicians of Great Britain and Ireland. In 1925–6 he was a member of the Royal Commission on Lunacy Law and Administration.

For the following appreciation we are indebted to two colleagues.

Two years after beginning practice in Newcastle David Drummond succeeded Dennis Embleton on the staff of the Royal Infirmary as honorary physician. His colleagues at that time were George Hare Philipson, Byrom Bramwell, and Charles Gibson. When Bramwell migrated to Edinburgh in the following year Drummond took over the post of honorary pathologist to the hospital, and for more than sixteen years found therein one of his greatest interests. Although in his early days he devoted much time to the study of diseases of the brain and cord, his work ranged widely, and he was a pioneer in other fields of clinical medicine. One of the first to recognize and lay down the association between empyema and pneumonia, he also taught the syphilitic origin of general paresis and aneurysm for many years before actually publishing his belief in his Address in Medicine to the British Medical Association at its Annual Meeting in 1895. He was essentially a pathologist physician, and to the end of his long and distinguished career a constant and welcomed visitor in the post-mortem room.

Sir David Drummond was an outstanding representative of a rapidly disappearing class—the older school of true general physicians of whom the profession is so justly proud. The less strenuous times of fifty years ago, when he was laying the foundations of his reputation, doubtless gave opportunity for development and culture which to-day we lack. There are now facilities for scientific progress in medicine which were then wanting, but the circumstances of modern life leave little time for the study of medicine as a fine art, and the cultivation of the manner and grace of Drummond's heyday. No appreciation of Physician Drummond as he was known throughout the North would be adequate without a reference to his invariable and unstudied courtesy, his consideration for others, his genuine sympathy, and generous help to all in need of it. Apart from the justified confidence in his professional attainments, his qualities won for him the respect and love of many friends.

No man consistently held to higher ideals of the duty of a consulting physician in relation to medical ethics; none had greater pride in his profession. His skill and intuition in diagnosis remain a traditional memory among students of the Newcastle school, based as they were on accurate observation and treasured experience. He was at his best with the senior student and young graduate, for it was not always that the junior could follow the rapid steps which led to final diagnosis and prognosis.

Outside the bounds of professional work Sir David read much and was keenly interested in the questions of the day. Of the graver problems of life he spoke seldom, never lightly, and only to his intimates. His belief in the importance of physical fitness was exemplified in his mode of living and the ability to enjoy an open air life in the year of his retirement from active practice was his reward. Like his son Hamilton whose early death was such a loss to the medical school in Newcastle he was a lover of nature and the open spaces. In later years his garden at Marchbankwood was in abiding joy.

Throughout his long life he was a sportsman in the truest sense. In younger days first-rate at cricket he could tell when over 60 years of age enjoy a spell with bat or ball at the nets. Until quite recently he was a keen shot and tireless even over rough country.

The memory of Sir David Drummond as a universally honoured and cultured physician will be cherished by the community of the North of England whom he served, and in the record of the school of medicine he did so much to develop

R. B.
S. McD.

Professor GREY TURNER writes:

Sir David Drummond will always be gratefully remembered by a numerous succession of men now scattered all over the world who came under his influence either as students or house physicians or young practitioners, and each will remember him for his sound teaching, genial personality, and kindly influence and timely help rendered in one way or another. Drummond was a great clinician and clinical teacher who constantly taught and urged the importance of actual contact with patients. He was certainly best at the bedside or in the post-mortem room, for when the opportunity offered he was ardent to carry on the lines of clinical examination into the domain of naked-eye pathology. When I first came under his influence he acted in the dual capacity of honorary physician and pathologist in the old Royal Infirmary, and his keenness in both spheres was infectious. It certainly taught me the paramount importance of correlating the clinical findings with post-mortem examinations, and this was always uppermost in his own mind, and those who remember his Presidential Address at the Annual Meeting of the British Medical Association in 1921 will recollect that this was his theme. He was keenly interested in surgery—*not as an art but as a therapeutic measure*—and in those far-away days he was often readier than some of his surgical colleagues to invoke its aid in doubtful cases. His long and intimate collaboration with his friend and colleague Rutherford Morison was very fertile, and led to many notable enterprises. Their names will always be associated with the operative treatment of ascites in cirrhosis of the liver which by the by was an operation practised in Newcastle with much success until the day arrived when that particular type of disease seemed to largely disappear. It was always delightful to see Drummond at an operation on one of his own cases; no one was ever more enthusiastic and no one more anxious to unravel the pathology. Later in my career I was accustomed to meet Sir David in consultation and each case was an education for me. His example of youthful enthusiasm carried on into old age was in itself a perpetual stimulus which none could witness without being infected. An enormous consulting practice together with his hospital work and his duties in connexion with the medical school often involved him in overwork and many anxieties, but he always had the saving grace of humour, and this often came to his aid and cheered up those about him even in grim circumstances, and it was then that the delightful Irish brogue at other times almost imperceptible became so apparent. In dealing with patients he was habitually courteous and kindly, but on occasion he could be—to say the least of it—unmistakably emphatic, and by observing his methods of handling difficult situations young practitioners gained a great insight into the conduct of their work. All through the war and in the excessively busy years immediately afterwards his energy and capacity for labour were a constant example to us all. Sir David was a most devoted parent, and his chief delight was in the welfare of his family. One son was killed in the war, and another Hamilton Drummond, a surgeon of great promise, after distinguished service in France was killed as a result of a motor car accident in 1925, while a third son, also a war veteran, Dr. Horsley Drummond, *is one of the honorary* physicians to the Newcastle Royal Victoria Infirmary.

D. WELLS PATTERSON, M.B., M.R.C.P.

Consultant Physician Hospital for Diseases of the Skin, Newcastle-upon-Tyne

We regret to announce the death on April 26th of Dr. David Wells Patterson, well known as a dermatologist in the North of England. He was born at Rickmansworth in 1871, and after studying medicine at Newcastle upon Tyne graduated M.B., B.S. at the University of Durham with first class honours in 1897. While an undergraduate he revealed an aptitude for leadership and was elected first president of the Students Representative Council. His academic distinctions included the Armstrong and Charlton scholarships and the Gibson prize. After graduation he spent some years in general practice and put this time to good use not only in gaining medical experience but in the acquirement of a knowledge of men and affairs.

In 1907 Dr. Wells Patterson gave up general practice in order to devote himself to dermatology and was elected physician to the Newcastle Hospital for Diseases of the Skin and assistant physician to the department for that specialty at the Royal Victoria Infirmary. He transferred to the side of general medicine at the Infirmary in 1913 and was appointed honorary assistant physician in which capacity he served until his retirement at the end of last year under the age limit. He obtained the diploma of M.R.C.P.Lond. in 1914 and was for two years president of the Newcastle upon Tyne Clinical Society. During the great war he served first as registrar and later as commanding officer of the 1st Northern General Hospital *with the rank* of lieutenant-colonel R.A.M.C.(T.) and afterwards had charge of the special military surgical hospital at Newcastle. In these posts he showed his gift for administration and was rewarded with the O.B.E. After the armistice he served as consulting physician to the War Pensions Hospital.

At the Annual Meeting of the British Medical Association held in Newcastle eleven years ago Dr. Wells Patterson was vice-president of the Section of Dermatology. He was a man of genial and energetic personality and will long be remembered by his colleagues as an organizer of medical meetings and dinners.

Dr. ARTHUR EDWARD SPROULLE, who died at Rotherfield, Sussex, on April 18th, came of a family of doctors, his father Dr. Thomas Sproulle and his four brothers being medical men. Qualifying L.R.C.P. and S.Irel. at Dublin in 1889, he settled at Withernsea, Yorks, then little more than a fishing village, in 1892 and for thirty-eight years carried on his practice there. When the village became an urban district in 1898 he was appointed medical officer of health, a post he held until his retirement on account of ill-health in 1930. For a large part of the time he was the only doctor in the town and there is no doubt that continuous overwork, particularly during

the war years when he attended large numbers of troops laid the foundations of the illness which caused his death at a comparatively early age Professionally he was a sound and careful physician and the respect in which he was held by his colleagues was shown by their electing him chairman of the East Yorks Division of the British Medical Association and later in 1922 of the East Yorks and North Lincolnshire Branch He held numerous medical appointments including that of medical officer to the Hull and East Riding Convalescent Home and Sanatorium He raised and trained a division of the St John Ambulance Association he was local agent for the Shipwrecked Mariners Association and a member of the crew of the Withernsea lifeboat—rowing in the boat to a number of shipwrecks A colleague writes To know Sproulle was to love him His striking personality and charm of manner immediately gained the confidence of his patients While no call from a really sick person however poor was refused he was inclined to be intolerant of the patient with an imaginary illness so that though retiring a comparatively poor man he leaves behind the love and respect of hundreds

---

Dr GEORGE CHARLES WALKER who died at Exmouth on April 27th was born at Kirkwall Orkney in July 1837 He received his medical education at Guy's Hospital and Liverpool and obtained the M R C S in 1860 graduating M D St Andrews in the following year After qualifying he served as honorary medical officer to the Liverpool Northern Dispensary and assistant house surgeon to the Chester General Infirmary and subsequently became honorary consulting physician to the Bootle Borough Hospital He practised for many years in Southport until his retirement to Exmouth about twenty years ago Dr Walker had been a member of the British Medical Association since June 1866 and was a former chairman of the Southport Division He was also one of the original members of the Southport Medical Society He was highly respected by his professional brethren and though he never took a very prominent part in local professional matters any remarks he made at meetings were listened to with attention and his opinions carried weight He is survived by three sons all members of the medical profession and two daughters

---

Dr JOHN STRATTON BROGDON of Hartlepool who lost his life in a rock climbing accident on Dow Crag near Coniston aged 31 was the son of Alderman J H Brogdon of Hexham He received his medical education at the Newcastle College of Medicine and graduated M B B S Durh in 1921 He began practice at Hartlepool in 1923 where he held the appointments of honorary radiologist at the Hartlepools Hospital and surgeon to the police Dr Brogdon was a very popular member of the Hartlepools Division of the British Medical Association and was to have been nominated as the next chairman of the Division The funeral which took place at Hexham was attended by prominent public men in the district as well as members of the medical and clerical professions Wreaths were sent by the Hartlepools Division of the British Medical Association the Mayor and Corporation the hospital staff and the local police force

---

Dr AUGUSTUS HENRY G JOHNSTON of Scunthorpe died on March 24th while on a visit to London at the age of 68 years He was a native of Westmorland and received his medical education at the school of the Royal College of Surgeons in Ireland He obtained the diploma of L R C S I in 1885 and afterwards took the L R C P I and L M He began practice at Scunthorpe about twenty years ago and subsequently became deputy medical officer of health At the annual meeting of the Scunthorpe War Memorial Hospital held on March 30th the chairman referred to the great assistance rendered to the hospital by Dr Johnston

The following well known foreign medical men have recently died Dr GUSTAVE ARCHAMBAULT professor of dermatology at Montreal aged 48 Dr BURTON ALEXANDER RANDALL emeritus professor of otology at the Philadelphia School of Medicine aged 73 of heart disease Dr NICOLAS CHARLES formerly director of the Maternity Hospital at Liége the first occupier of the chair of gynaecology and obstetrics in the university and founder and editor of the *Journal d Accouchements* aged 87 Dr JAMES RIDDLE GOFFE emeritus professor of gynaecology past president of the American Gynaecological Society aged 80 Dr FELIPE PUIG formerly president of the Uruguay Society of Phthisiology Dr CARLOS E KOHLY Y FERNANDEZ director of *Revista Medica Cubana* Dr PAUL CHARMEIL honorary dean of the faculty of medicine and pharmacy of Lille aged 71 Dr MERIDA NICOLICH an eminent ophthalmologist of Malaga Dr C DEBIERRE honorary professor of the Lille faculty of medicine and corresponding member of the Academie de Medecine and Professor E KAUFMANN a morbid anatomist of Gottingen aged 72

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The House of Commons has this week discussed the Police and Prisons Services and the new Import Duties

A National Health Insurance Amendment Bill will be introduced by the Government in the House of Commons before the Whitsun Recess

Agriculture Estimates Foot and Mouth Disease and Tuberculosis

In introducing on April 28th the Estimates for the Ministry of Agriculture and Fisheries Sir JOHN GILMOUR said investigations had continued into foot and mouth disease He did not claim that the main problem had been solved but progress had been made in directions which enabled the Department to control and deal adequately with outbreaks when they occurred Slaughter was still the only safe and satisfactory way of dealing with the outbreaks of which there had been ninety-ten in this country during the year 1931 In the first quarter of 1932 there had only been one outbreak In April the disease occurred in Kent but there was every hope that it would be confined to a small radius Where animals had not been directly exposed to infection the Department had tried inoculation with serum During 1931 5,525 animals associated with twenty three outbreaks were so inoculated and disease followed only in two of the lots treated It was not possible to be certain of the effects of this treatment

Mr GLOSSOP complained that compensation for a tuberculous cow was lower if when slaughtered the animal proved to have generalized tuberculosis He considered that a cow with advanced tuberculosis in one organ might be a more dangerous source of infection Under the present system of compensation there was no inducement for the owner to notify the local authority on the first suspicion of tuberculosis When it was obvious that the animal would soon die the owner notified it because he knew the compensation would be more than the price he would get from the knacker The object of compensation was not to give money to farmers but to get infected animals notified and slaughtered as early as possible so as to eliminate the scourge He asked the Minister to reconsider the methods on which compensation was paid He also thought the time had come when the Minister should try to secure the production of milk of a higher butter fat content In North America and in Europe milk was sold on its butter fat content

Replying to the debate Sir JOHN GILMOUR regretted that for the present he could not give the grant previously promised for the rebuilding and development of the Royal Veterinary College He trusted this was merely a postponement The authorities of the College had enough funds in their hands to make a beginning

Road Accidents

Mr PYBUS told Mr *Tinker* on April 28th that he had considered the possibility of collecting the number of accident cases under Section 36 Sub-section (2) of the Road Traffic Act 1930 where hospital treatment had been given to injured persons but regretted that the information would not justify the time and labour involved Asked by Sir JOHN HASLAM if he had any reason to doubt figures provided by the British Medical Association showing that only 10 per cent of the money expended by hospitals was recovered from insurance companies Mr PYBUS said he had no information to show that insurance companies were evading the provisions of the Act

Replying to Lord Apsley on April 27th Sir HILTON YOUNG said he would consider whether medical officers of health throughout the country should be asked to distinguish in their reports between deaths from road accidents and all other deaths from violence and accident

Sir H SAMUEL told Dr Salter on April 27th that he could not give the number of children under 14 killed on the public highways by motor vehicles during 1931 as the returns were not classified under age categories The number of persons charged with manslaughter in connexion with deaths due to motor accidents had not hitherto been collected

he would see whether means could be devised to collect and publish this information in future

On May 2nd on a vote for police in England and Wales the Home Secretary Sir HERBERT SAMUEL said the number of persons killed in Great Britain in road accidents last year was 6 691 and the number injured was 202 119 Every day of the year 18 persons were killed and 553 were injured on the roads Fatal accidents last year showed a reduction on the previous year of 614 Non fatal accidents showed an increase of 24 224

The Deaf and Dumb

Sir HILTON YOUNG told Mr Price on April 28th that he could not undertake to introduce legislation providing assistance for the deaf and dumb on lines similar to that given to the blind under the Blind Persons Act

In reply to Dr Fremantle on the same day Sir D MACLEAN said he had received a report from a late medical inspector of the Board of Education who had been appointed in conjunction with the Ministry of Health to ascertain the condition of the deaf in England and Wales The report was not intended for publication and was still under consideration by both Departments

Cholera in India

Presenting the India Office Estimates on April 29th Sir SAMUEL HOARE said he could report definite improvements in health Leprosy surveys were being continued and had increased the number of cases treated in clinics There were over 24 000 such cases in the Central Provinces and 28 272 in Madras a decade ago only 8 000 lepers were cared for in the whole of India For dealing with cholera a bacteriophage had been discovered This minute parasite growing in the cholera bacillus could now be isolated for obtaining a pure culture The varieties obtained had the power to destroy the bacilli of cholera rapidly and were added to the water supply where cholera had broken out or was likely to break out This had been done in the last twelve months in the Nawgong district of Assam In the area dealt with practically no cholera appeared in this cholera season nor in the last two cholera seasons If this was confirmed by further observation it would be a most important advance In the malaria survey also an advance had been made in the last year

Observation Centres for Juvenile Offenders and Prison Dietary

The House discussed on May 2nd a vote for the Prison Commissioners and the prisons in England and Wales Dr SALTER urged that juvenile delinquents should be remanded to an observation centre where their mental and physical condition could be discovered The necessity he said was more urgent having regard to the cases which were unfortunately increasing in proportion to the whole where mental moral and physical damage had been caused by encephalitis lethargica He knew of two adolescents who were suffering from the disease and had been sent to prison whereas if they had been remanded to an observation centre their condition would have been discovered One of them died in prison from the after effects of the disease The other had paralysis of the muscles of the eyeball and other physical signs which would have led to instant detection and altogether different treatment had measures recommended by the Departmental Committee been carried out He could also give the Home Secretary particulars of the case of a young man who was suffering from juvenile general paralysis of the insane He was in prison some months before he was removed to an asylum Belgium had admirable observation schools and a carefully graded system enabled the specialists who controlled the institutions to decide what particular after treatment was required As a result the whole attitude of the authorities towards juvenile offenders had been modified At the London County Council last week there was a prolonged debate on the subject and it was agreed on all sides that development in the direction he had indicated should be carried out He hoped that Sir H Samuel would give his personal attention to the matter Referring to the question of prison dietary Dr Salter said the supply of green vegetables particularly uncooked green vegetables in prison was extraordinarily small and deficient He spoke with some experience of the matter because he had been in prison on more than one occasion It might be said that these were luxuries to which no prisoner was entitled In view of modern knowledge as to the detrimental results of the deprivation of these vitamins they ought to be supplied to every prisoner He asked the Home Secretary to consult his medical advisers in the hope that prison dietary would be augmented or modified

Mr W HUTCHISON said that he recently visited the Maidstone gaol and asked the medical officer questions about the prisoners diet The medical officer informed him that it was a scientific diet and that it had been discovered that prisoners for a short time after entering prison lost weight Then they came to a point at which their weight went up and they became more healthy in the majority of cases than they had ever been before they came into prison

Sir H SAMUEL said that Dr Salter had spoken of the necessity for observation homes particularly for children and in London and for special attention being given to the individual characteristics of the children and other delinquents so that medical or other measures might be adopted and he was right in the view he had expressed The present remand home in London was not satisfactory but that was a matter requiring legislation It concerned the London County Council also and if Dr Salter could persuade the Council to take a forward view on the matter no one would be more pleased than the Home Office or more ready to assist their efforts The prison dietary had been framed after careful medical investigation and as a rule prisoners put on weight considerably after they entered gaol no vadays but he would draw the attention of his expert advisers to the point raised by Dr Salter with regard to the inclusion of fresh vegetables

The debate was adjourned

National Radium Trust

On May 3rd Sir F GRAHAM LITTLE asked the Lord President of the Council if any modification had been made in the terms of the Charter of Incorporation of the Radium Commission by which it was required that one half of original members of the Commission selected by lot should go out of office after a certain date and the remaining original members at a later date Mr BALDWIN in reply said that this requirement in the Charter of the National Radium Trust was varied by a supplemental Charter granted to that body on July 23rd 1931

Mines Vote Debate

The House of Commons in Committee of Supply on May 3rd discussed the vote for the Mines Department of the Board of Trade Mr ISAAC FOOT the Secretary for Mines said that in 1931 the number of accidents gave some ground for encouragement The number of deaths which occurred in the coal mines last year was the lowest in the history of the Department—namely 8s9 which was 0 9 per cent of the men employed or 3 77 for every 1 000 000 tons raised Serious accidents numbered 3 304 the lowest on record All accidents numbered about 140 000 That was 26 000 less than in 1930 and 36 000 less than in 1929 Everything must be done that science could do to make big disasters impossible but the real trouble was the daily wastage Taking the ten years from 1920 to 1929 for every one casualty that arose from explosion there were 1 103 from other causes the most prolific being falls of ground A substantial reduction in accidents could be brought about by the use of protective equipment which one day would be adopted Last year thirty nine boys under 16 years were killed in the mines and over 7 000 were disabled by injury for more than three days There was urgent need for more instruction and education

Captain R T EVANS said that recently a body of doctors expert in the treatment of lung diseases had made inquiries into what they called coal miners lung disease The situation which was disclosed from that pathological and medical investigation was disturbing It used to be thought that coal dust blackening of the lung was in a way a protection against other probable lung diseases but they knew to day that the intrusion of coal dust rendered the victims peculiarly vulnerable to diseases like bronchitis and tuberculosis He had been staggered by the small percentage of miners suffering from lung troubles who received any compensation and he

appeal for an alteration in the regulation governing the ward

Replying to the debate Mr Loot said that the Ringrose safety lamp was being carefully tried in a large number of pits

National Birth Control Conference.—Mr J Brow replying to Mr Potter on April 26th said that the Minister of Health had received and had now under consideration an application from one local authority for sanction for one of its medical officers to attend the conference of the National Birth Control Association in London in the near future

Birth Control Clinics.—Mr Ernest Brow replying to Mr Lever on April 3rd said that clinics for contraceptive advice did not form an integral part of the maternity hospital to which the Ministry of Health distributed grant in aid Grants from the Exchequer were no longer paid direct to maternity hospitals except for the training of midwives

Diacetylmorphine Manufacture in Britain.—Sir Herbert Samuel told Mr Cranfill on April 27th that 14 903 oz of opium and 12 525 74 oz of coal in 2 011 06 cwt of morphine 3 426 oz of diacetylmorphine) 46 560 74 of morphine all told and all and no person had been employed in Britain during the twelve months ended December 31st last The production was not in excess of the requirements for medical and scientific purposes and the Government for the limitation of the manufacture of narcotic drugs was not operative in Great Britain Sir H Samuel told Dr Ironside on April 28th that it was the intention of the British Government to ratify the 1931 Convention for the limitation of the manufacture of narcotic drugs and to enable this to be done the Dangerous Drugs Act 1932 was passed in order to bring the law into conformity with the provisions of the Convention

Silicosis Replies to Mr Tinker on April 27th Sir Herbert Samuel said that silicosis was not notifiable to coal mines but that the returns under the Workmen's Compensation Act showed that in 1930 there were twenty cases in which coal miners received compensation for disablement from silicosis So far as I know only one of these cases occurred in Lancashire and the Medical Board set up in June last has not yet issued any certificate in respect of any coal miner in Lancashire

Mental Defectives (Children) in Elementary Schools.—Sir Donald Maclean told Mr Rhys Davies on April 28th that during the last few years for which returns were available there had been practically no variation in the proportion of children in public elementary schools formally ascertained by school medical officers to be mentally defective but these figures could not be used as a reliable guide owing to the absence of uniformity of standard and other difficulties

Opium Manufacture and Distribution in India.—Replying to Mr Rhys Davies and Mr Cranfill on May 2nd Sir S Hoare said that the distribution and sale of opium in the Provinces of British India was under the control of Ministers responsible to their respective Councils The amount of opium manufactured at Ghazipur for consumption in India depended on the demand from the Provinces There had been a substantial and progressive reduction in recent years The Government of India sold opium for consumption in India to local Governments at cost price

Horses and Dogs for Experimental Purposes.—On May 2nd Mr Duff Cooper replying to Lieut Colonel Applin said that eight horses were used for experimental purposes at the Chemical Defence Experimental Station Porton in 1930 Apart from these no horses or dogs were used for experiments in connexion with chemical defence either at Porton or Cambridge during 1930 and 1931

Milk Reorganization Committee.—Sir Hilton Young states that any proposals for legislation relating to the composition of milk must be postponed pending the recommendations of the Milk Reorganization Committee which has just been announced

Factory Inspectors Report.—The Home Secretary will endeavour to expedite the publication of the Factory Inspectors Report for 1931 to permit a Parliamentary debate before the House of Commons rises in July

Medical News

The 101st annual meeting of the British Association for the Advancement of Science will be held this year at York from August 31st to September 7th inclusive under the presidency of Sir J Alfred Ewing The inaugural meeting of the British Association was held at York in September, 1831, and three further meetings have been held there

The next quarterly meeting of the Royal Medico Psychological Association will be held at 11 Chandos Street W on Thursday May 19th at 2 30 p m Dr Edwin Goodall will open a debate on the following proposition The exciting cause of certain states of disease at present classified under 'schizophrenia' by psychiatrists may be infection The pathogenesis of these states does not in this country receive the close prolonged and co-ordinated clinical and pathological study which it demands

A popular lecture on "Polar lights" will be given by Professor Sydney Chapman J R S to members of the British Science Guild and others on Wednesday May 25th at 4 30 p m at the Royal Society of Arts John Street Adelphi Tickets for which no charge is made can be obtained from the secretary British Science Guild, 6 John Street W C 2

The University of London Medical Graduates Society is holding its annual meeting and dinner at the Langham Hotel on *May 11th* Tickets (price 12s each) can be obtained up to May 9th from the honorary secretaries at 11 Chandos Street, W 1

At the festival dinner of the Corporation of the Sons of the Clergy to be held at Merchant Taylors Hall L C on May 25th Lord Moynihan P R C S will be among the principal speakers

A dance organized by the Ladies Guild of the Royal Medical Benevolent Fund is to be held on Thursday June 9th in the Great Hall of the British Medical Association Tavistock Square W C This function will be the thirteenth of a series which in the past have proved both successful and enjoyable and the committee is most anxious that members of the medical profession and others interested in this Fund should lend their support Tickets (single 6s double 11s) may be obtained from Mrs Oldershaw 26 Upper Wimpole Street W 1

The annual meeting of the British Dental Hospital will be held at the rooms of the British Dental Association 23 Russell Square, W C on Thursday May 19th at 8 p m with the president Sir Norman G Bennett in the chair

The next meeting of the Biochemical Society will be held in the Department of Biochemistry Oxford to day (Saturday), May 7th, at 2 30 p m

At a meeting of the Harveian Society of London in the Paddington Town Hall on Thursday May 12th at 8 30 p m Dr Geoffrey Holmes of Harrogate will give an illustrated lecture on spa treatment with special reference to British spas

A post graduate course on neurology and psychiatry with special reference to treatment, will be held in Vienna from May 30th to June 11th when lectures will be delivered by Professors Eiselsberg Wagner Jauregg Wenckebach Jellinek and Froschels among others Further information can be obtained from Dr Kronfeld Porzellangasse 22 Wien IX

A course of demonstrations in neurology for candidates for the M R C P examinations will be held on Mondays and Fridays from May 20th to July 11th at 6 p m at the National Hospital Queen Square W C 1 Fee for sixteen demonstrations £6 6s Special terms can be arranged for those unable to take the whole course Application should be made to the secretary

The Fellowship of Medicine has arranged four similar courses in medicine surgery and the specialties at the Prince of Wales's Hospital Tottenham from May 23rd to June 4th June 6th to 18th June 20th to July 2nd, and July 4th to 16th Four lecture demonstrations on ante natal treatment will be given by Dame Louise McIlroy at the Royal Free Hospital on Wednesdays June 1st to 22nd Gynaecology will be dealt with at the Chelsea Hospital for Women from June 6th to 18th and during the same period a course in diseases of the chest will be held at the Victoria Park Hospital Three epidiascope and laboratory demonstrations will be given at 10 Bedford Square on May 18th 25th and June 1st at 8.30 p.m. Professor Arthur Hall will give three lectures on epidemic encephalitis at 8.30 p.m. on June 2nd 9th and 16th An evening course of practical demonstrations for M.R.C.P. candidates will be given at the National Temperance Hospital on Mondays and Fridays June 6th to July 1st Application for all syllabuses should be made to the Fellowship of Medicine 1, Wimpole Street W.1

The second German Congress for Psychical Hygiene will be held at Bonn on May 21st when the principal subject will be the eugenic aims of psychical hygiene Further information can be obtained from Dr. Koester Kolner strasse 208B Bonn

The twelfth International Neurological Congress will be held at La Salpetriere Paris on May 31st and June 1st when a discussion will be held on recent advances in the knowledge of epilepsy introduced by Drs. Foerster of Breslau Pagniez of Paris Abadie of Bordeaux and Crouzon of Paris

The tenth International Congress of Psychology which will be held at Copenhagen from August 22nd to 27th is to be followed by tours of inspection to German and Austrian institutes of psychology An advance programme is available, and early application by those who intend to take part should be made to Professor D. Katz 13 Moltkestr., Rostock (Meckl.) Germany

The French National League against Alcoholism recently celebrated in the amphitheatre of the Sorbonne under the presidency of Professor Achard the thirtieth anniversary of the anti-alcoholism movement in the schools which was founded by Dr. Roubinovitch who was presented with the grand diploma of the league

A conference of medical students on medical missionary work in the Tropics will be held at the London School of Hygiene and Tropical Medicine Keppel Street (Gower Street) W.C. on Tuesday May 10th from 3.30 to 7 p.m. The annual medical missionary breakfast of the Medical Prayer Union will be held on Wednesday May 11th, at the Refectory University College Gower Street at 8 a.m. An address will be given by Dr. C. C. Chesterman of Yakusu Congo Belge W. Africa Those wishing to be present at either of these gatherings are asked to notify Dr. Tom Jays Livingstone College Leyton E.10

This week's issue of *Nature* dated May 7th contains an appreciative article by the Duc de Broglie upon the scientific career and work of Lord Rutherford O.M. F.R.S. Cavendish professor of physics University of Cambridge It forms part of the series of Scientific Worthies and is accompanied by a photogravure plate portrait of Lord Rutherford

Drs. C. W. Buckley J. B. Burt and W. Shipton after twenty years' service on the active honorary medical staff have accepted the invitation of the committee of management of the Devonshire Hospital Buxton to remain on the staff for a further five years

The Minister of Health with the approval of the Prime Minister has appointed Sir Arthur Lowry C.B. to act as Deputy Secretary to the Ministry of Health while Sir E. Strohmenger K.B.E. C.B. is seconded for service in the Treasury

Applications for the Norma Macleod studentship in biochemistry must be sent to the secretary of the Lister Institute of Preventive Medicine Chelsea Bridge Road S.W. by June 1st with details of scientific training and career together with the names of two personal referees The studentship is of the value of 100 guineas per annum and is tenable for one year but renewable Candidates must have had a thorough training in chemistry and some knowledge of biology is desirable but not essential

The Import Duties Advisory Committee announces that applications whether in relation to additional duties or to the Free List should be made so far as possible by representative bodies of the trades concerned The committee does not propose to proceed as a rule by formal hearings Applicants therefore should submit their case fully in writing and supplementary statements if required will be called for The committee will give public notice of cases in which it is considering the imposition or modification of 'additional' duties or of variations of the Free List in order that interested parties may make representations which should be addressed to the secretary Import Duties Advisory Committee Caxton House (West Block) Tothill Street S.W.1

The centenary of the birth of the syphilologist Professor Alfred Fournier who died in 1914 will be celebrated in Paris from May 8th to 12th under the patronage of the President of the French Republic A general assembly of the International Union against the Venereal Peril will be held on the 8th the Albert Fournier Institute will be inaugurated by the Minister of Public Health on the 9th and on the following days lectures on various aspects of syphilis will be given at the Hopital St. Louis to which Fournier was attached

To commemorate the centenary of Goethe's death the German Society for Medical Tours has organized a spring tour to Thuringen starting at Weimar on May 19th and ending at Friedrichroda on May 28th The inclusive cost will be provisionally RM. 190

Sir Michael O'Dwyer has been appointed by the National Institute for the Blind to serve as its representative on the Committee of the International Association for the Prevention of Blindness

QUERIES AND ANSWERS

End results of Prostatectomy

DR. ARTHUR RICKETTS (London W.) writes: I should be greatly obliged to any medical man if he could inform me of any authentic case of a man becoming the father of a child after the operation of prostatectomy had been performed upon him I cannot find any mention of such a case in any book including Rendall Short's *Index of Prognosis and End results of Treatment* or in the reports of Mr. Freyer's cases or those of Sir J. Thomson Walker I am making this query because I believe it has never been given an authoritative answer

Sunburn

SURGEON writes I should be grateful for advice as to the best treatment of acute sunburn of which as a ship surgeon on short pleasure cruises I see many cases Iced calamine and zinc oxide lotion with a thin water basis gives temporary relief but often fails to prevent blistering I should appreciate opinion as to the advisability of adding glycerin to the above and as to the efficacy or not of any preparation such as cocoa oil

Plantar Corns

D CHIROPODIST (Bath) writes in reply to CHIRUS I would recommend treatment on the lines adopted for the case mentioned below A deep seated horny growth in the head of the foot causing considerable pain and lameness in spite of frequent treatment with caustic has points to speedy removal by the following Sodium salicylate was applied for two nights before attending for treatment The affected epidermis was then scraped away till the raised surface responsible for the growth was reached and this was treated by daily applications of salicylate of sodium till a firm callus had formed over the whole surface Ten days later the hollow formed by the scraping had completely filled up and healthy skin replaced the horny layer If the scraping of the softened epidermis is not thorough enough at the first attempt the whole process may be repeated in ten days time I should be interested to hear other suggestions

DR ERNEST H BROWNE CURRIE (London) writes Plantar corns of the ordinary type of corns of the vertex and—the latter being especially troublesome and resistant to ordinary remedies—tending to recur even after excision—can usually be permanently cured by the judicious application of radium The case referred to by me in a letter to the *British Medical Journal* a long time ago was March 14th 1908 The cure was satisfactorily I was perfectly normal to all appearance unless of course the patient came under the influence of radium which I only mention would expect to happen There is no pain or any discomfort in the treatment if care is used but I have in the first application usually found that the pain was much I should not entirely gone

Unilateral Oedema

DR JOHN A JOHNSTON (Wembley Park Middlesex) writes In reply to the query by O J regarding the treatment of unilateral oedema (April 23rd p 784) I would venture to say that the advisability of operative treatment has been established I have seen beneficial results follow in a similar case from Sistrunk's operation which consists in removing a long strip of tissue from the thigh and lower leg the thrombosis is marked it is possible that periarterial sympathectomy might have the desired effect

Income Tax

Depreciation and Obsolescence

"D L" replaced his car in October 1931 The cost price of the old car has been reduced by the aggregate depreciation allowances thereon to £168 and £147 was allowed for it against the price of the new car The inspector of taxes is willing to allow the difference of £21 as obsolescence and depreciation on the new car is from the date of purchase Can anything further be claimed?

*** No D L has received an allowance for the total cost of the old car less the £147 in the aggregate of the depreciation and obsolescence allowances and is now beginning to receive similar treatment in respect of the new car It is true that his out of pocket expense was £118 to purchase the new car but to some extent he will have to wait for the operation of the depreciation allowance in future years to give him full recoupment

Public Appointment Expenses

"W J M" inquires whether the following expenses are allowable (1) expense of obtaining a special diploma (2) subscription to an association (3) cost of purchasing books and instruments

*** (1) No such expenses are capital outlay (2) only if the membership is required by the terms of W J M's appointment (3) only to the extent necessary to maintain (but not to improve) the reference library and stock of instruments

Professional Expenses

R K asks for a reference to any leaflet etc setting out the allowances or proportions of allowances usually conceded in connexion with the running expenses of his practice

*** The circumstances of practices differ so much that no useful flat rates or proportions can be laid down for general use and we know of no leaflet that would be helpful The matter was however dealt with rather more fully in a small handbook recently reviewed in the *Journal*—namely *Income Tax and the Professional Man* published at 4s 6d net by Crosby Lockwood and Co

LETTERS, NOTES ETC

First-aid Classes

MR IVOR M HUBBACK M A (Principal of Morley College for Working Men and Women 61 Westminster Bridge Road S E 1) writes We are wanting to start a class here in first aid on Friday afternoons in connexion with a scheme for providing classes for unemployed men and women Unfortunately we are entirely without funds for paying lecturers and are having to rely on the generosity of those who have volunteered to help We have not however as yet heard of any doctor able and willing to spare an hour or two in the afternoon to take a first aid class Several would be students have indicated their wish to attend and we very much hope to be able to arrange for a class to take place I am venturing to ask any of your medical readers whether they can help

Medical Golf

The summer meeting of the Medical Golfing Society will be held on Thursday June 9th at Walton Heath Lord Riddell invites all competitors to be his guests for the day The knock out tournament for the Milsom Rees Challenge Cup has reached the semi final stage Rowley Bristow v Lindsay Ker and Major Strachan R A M C v Squadron Leader Brown

Doctors and District Nurses

COUNTRY PRACTITIONER writes I agree with Dr Barford when he says this sort of thing is happening all over the country and that the British Medical Association ought to take the matter up In addition to maternity irregularities my own experience is that the district nurse is diagnosing and treating skin diseases in children infections and otherwise as a regular practice A short time ago I had a child brought to me with profuse salivation and was told that the nurse had been treating it for five weeks for an eruption of the face I sent this child to hospital where it died (as I was informed a short time later) of meningitis Only last week a mother brought her child with a chicken pox rash just beginning to clear and stated that she came because there was no nurse owing to a change of nurses On account of this change the man removing furniture from the nurse's quarters asked me what should be done with all the drugs there? Surely such practice by a district nurse constitutes a danger to the public

Motorists and Conveyance of Goods

The ruling of the High Court in the appeal of the Automobile Association against the conviction of a Cardiff motorist for conveying goods in a private car has created a situation of importance to every private car owner The A A is advised that it was never the intention of Parliament that the statutes should be interpreted in this way and it is suggested that the decision of the High Court is contrary to the letter and spirit of the law on the subject The point is a simple one Under the schedules of taxation it is provided that for a vehicle to be taxed on weight—that is as a commercial vehicle for carrying goods—it must be "constructed or adapted for use and used for the conveyance of goods or burden of any description whether in the course of trade or otherwise" The Finance Act of 1922 provides that where a vehicle has been taxed on one basis and is subsequently altered or used in such a manner as to bring it into a higher taxable class then the increased tax shall be paid Thus in order to bring the private car into the higher class it must not only be used for goods carrying but also be constructionally adapted or altered for that purpose This is the effect of the view strongly expressed by Mr Justice McNaghten in dissenting from the decision of the other members of the court The Automobile Association is informed that the whole matter is already under the urgent consideration of the Minister of Transport and it is believed that measures will be taken to regularize the position of private car owners

Vacancies

Notifications of offices vacant in universities medical colleges and of vacant resident and other appointments at hospitals will be found at pages 50 51 52 53 54 55 58 and 59 of our advertisement columns and advertisements as to partnerships assistantships and locumtenencies at pages 56 and 57

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 231

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

408 Chronic Miliary Tuberculosis

J SIMON and C CARRASCO (*Prensa medica* December 1931 p 15) who record two illustrative cases state that in recent years a chronic miliary pulmonary tuberculosis has been described its existence having been discovered by radiographic examination Engel has described two forms the first characterized by an acute febrile onset and the other which is less frequent by a sluggish and afebrile course and more favourable prognosis The authors first patient was a boy aged 2½ years who during an attack of pulmonary tuberculosis showed evidence of a miliary dissemination throughout both lungs accompanied by severe constitutional disturbance The general symptoms however gradually subsided although the radiological signs persisted and were still present though considerably lessened two years after the onset The second patient was a girl aged 6 years who had been exposed to tuberculous infection but did not show any clinical symptoms of the disease Radiography however showed the presence of miliary tuberculosis After a few months hygienic and dietetic treatment considerable clinical and radiological improvement occurred so that the case corresponded to Engel s second form

409 Seminal Vesiculitis in Mumps

A VALERIO (*Arch Bras de med* November 1931 p 539) records the case of a man aged 22 who contracted bilateral mumps of which he had had a previous attack at the age of 6 years Five days after the onset he developed pain in the hypogastrium and a sensation of weight in the anus and perineum A few hours later he had a spontaneous and very painful blood stained ejaculation with an increased feeling of tension in the rectum The temperature was 102 4° and the pulse 112 Micturition was frequent and very painful with an occasional terminal haematuria On rectal examination the prostate was found to be normal but both vesiculae seminales were extremely tender swollen and nodular and gave issue on pressure to a muco sanious discharge No gonococci were found and there was no evidence of syphilis Rapid recovery followed treatment by rest warm applications to the abdomen and rectal analgesic suppositories

410 Unusual Gonococcal Sequels

B M BAKER jun and E P CARTER (*Bull Johns Hopkins Hosp* February 1932 p 57) record three cases of unusual sequels to gonococcal infection In the first case the patient being a negress aged 25 there ensued an acute polyarthritis with endocarditis organisms resembling gonococci were demonstrated in smears of the cervix and also in pus aspirated from one of the affected joints A grave general infection developed with delirium high fever tachycardia emaciation marked anaemia and leucocytosis with pneumonia as the terminal event The second patient a negro aged 54 had had acute gonorrhoea 35 years before admission to hospital when he presented a condition of arterio sclerosis hypertension and obstructive jaundice due as shown at the operation to a tumour in the head of the pancreas The development of continued fever with an aortic diastolic murmur leucocytosis general toxaemia and peripheral arterial embolism justified the diagnosis of acute aortic endocarditis Blood cultures both before and after death were sterile but the demonstration of Gram negative diplococci in smears from the aortic valve and of a Gram negative coccus in culture which would not grow on agar and did not ferment dextrose warranted the assumption that the endocarditis was gonococcal The third patient a negro aged 36 was admitted with acute abdominal symptoms leucocytosis and high fever Nothing abnormal was found at the operation apart from a slightly enlarged liver He had no pain or tenderness following the operation but pyrexia of a septic type with leucocytosis and progressive anaemia persisted On the eighteenth day blood cultures were reported positive a small Gram negative diplococcus having been demonstrated with difficulty Death followed on the thirty seventh day and at the necropsy an abscess in the right lobe of the liver was discovered from which definite Gram negative cocci and diplococci were recovered

411 D A PRENDERGAST (*Canadian Med Assoc Journ* February 1932 p 201) believes that acute endocarditis complicating gonorrhoea though far from common is not so rare as is usually thought Two cases one of which ended fatally are reported Except in respect of its better prognosis this condition does not differ markedly from other forms of acute bacterial endocarditis The greatest age incidence is between 20 and 40 years the period in which gonorrhoea is most frequent It occurs most commonly in the more virulent types of gonorrhoea where other complications such as epididymitis and arthritis are present The onset is usually characterized by fever chills sweating palpitation and prostration The cardiac lesions are those of any malignant endocarditis except that the vegetations and ulcerations tend to be particularly large The aortic valves are most frequently involved infarcts petechiae and pericarditis are common The diagnosis is based on the presence of signs of acute general infection with active involvement of the cardio vascular system Isolation of the gonococcus from the blood though affording positive proof is extremely difficult Acute endocarditis in a gonorrhoeal patient is indicative of gonorrhoeal endocarditis The treatment is unsatisfactory and must be chiefly symptomatic complete rest in bed might be of value in cases showing early signs of systemic infection Prendergast alludes to a case reported from Paris which was cured by the use of anti gonococcal serum

412 R J GERMAIN (*These de Paris* 1931 No 539) who records four illustrative cases states that pleurisy is usually a late complication of an attack of gonorrhoea which has not been recognized or neglected It is always secondary to gonococcal arthritis which it follows in from one to fifteen days In addition to signs of a pleural effusion an area of pulmonary congestion can almost always be detected at the apex or base The fluid is at first sero fibrinous it is characterized by an excess of polymorphonuclears and on cultivation yields a growth of gonococci and no tubercle bacilli Recovery may take place by crisis in two or three weeks or gradually by lysis In many cases however the issue is not so favourable other signs of septicaemia develop and death ensues At the post mortem examination the pleurae are found to be filled with pus and the lungs show septic infarcts Diagnosis is made by the negative result of inoculation of guinea pigs agglutination of gonococci by the patient s serum the complement fixation reaction and a positive blood culture

413 Spinal Complications of Typhoid Fever

L K WANG and L J MILTNER (*Chinese Med Journ* January 1932 p 1) discuss what they term typhoid spine and review its aetiology pathology diagnosis and treatment They then describe two recent cases The first patient entered hospital three months after an attack of diarrhoea and general malaise the Widal reaction on admission being strongly positive He complained of severe pain in the back and rigidity of the lumbar muscles there was no visible abnormality The man was obviously ill the pain persisted even when resting in bed and his temperature rose irregularly at times An x ray examination of the lumbar region revealed a destructive

lesion involving the contiguous surfaces of the bodies of the third and fourth lumbar vertebræ and the disk between them The patient was kept quiet in bed but the disease progressed until a month later he was placed in a plaster of Paris jacket From this time he did well New bone was laid down and seven weeks later the x-ray picture indicated that bony ankylosis was complete there was then neither pain nor tenderness in the area The second case was admitted to hospital a typhoid fever and after several complications including broncho-pneumonia in the fifth week and acute appendicitis in the eighth, he began to have severe pain in the back about the fifteenth week The entire lumbar spine was found to be rigid the pain being most acute over the right sacro-iliac joint No abnormality in the lumbar spine was found by x-ray examination but stereoscopic views showed smoothness in the region of the sacro-iliac joint Later x-rays showed definite erosion and involvement of the first and second lumbar vertebræ The pain was severe but was largely relieved by the application of a plaster of Paris jacket The subsequent progress was good and four months later he was able to do light work An x-ray examination then showed complete bony ankylosis and increased condensation of the sacro-iliac area

314 Vincent's Infection of Pleura and Vagina

H D Jeans and S J Stretch (*Journ Amer Med Assoc* January 16th 1932 p 219) who record an illustrative case of a fuso-spirochætal infection of the vagina and pleura state that reports of such infections of regions other than the mouth have been appearing more frequently of late especially those of the respiratory system but cases of fuso-spirochætal empyema are rare most having been secondary to some obvious underlying lung condition such as bronchiectasis lung abscess or pulmonary gangrene In the present instance however the case of a *previously healthy* woman *with no morbid* condition of the *lungs was detected* by clinical or radiological examination Vaginal infection with Vincent's organisms is also *rare* and the authors record their case as the only example on record of the association of pleural and vaginal infection due to Vincent's organisms and of recovery from the empyema in which they were found

Surgery

415 *Secondary Abscess following Appendicitis*

H Angerer (*Zentralbl f Chir* February 6th 1932 p 440) records two cases of abscess occurring six years after perforation of the appendix He remarks that while adhesions and bands recur frequently after appendicectomy the possibility of secondary abscess must be remembered since several cases have been reported The first patient was a man aged 24 who was admitted as a case of pneumonia He had had peritonitis after the operation but had worked regularly in the interval till he began to suffer from epigastric pain anorexia nocturnal pyrexia and malaise Symptoms of acute obstruction supervened with signs of consolidation at the right base The liver and spleen dullness were normal and there was a leucocytosis of 20 000 A pleural puncture yielded clear serum but three days later the fluid was sanious and contained many haemolytic streptococci Screening revealed a collection of gas below the diaphragm The seventh rib was resected, and a large subphrenic abscess *with its* wall formed by necrotic liver tissue was opened *Three* weeks later a pleural empyema was opened The *patient recovered* and in ten months had gained *22 lb* In the *second* patient a girl aged 20, a fistula persisted for several weeks after her operation She remained well for nine *months when* indefinite abdominal pain constipation *and* anorexia supervened followed by symptoms of *acute* obstruction A rounded tender swelling appeared *in* the right hypogastric region and there was a leucocytosis of 15 000 A large abscess containing seven pints of offensive turbid pus and lying between intestinal coils was opened A good recovery ensued Tubercle bacilli were not found in these two cases In the first there was no history of gastro-duodenal ulcer cholecystitis or dysentery and the subphrenic abscess occurred six years after appendicitis The author adds that general experience shows that when such abscesses occur, there is a considerable latent period between the primary and secondary lesion In the second case the abscess was probably secondary to the fistula that had persisted for some weeks after appendicectomy

416 Surgery of the Undescended Testis

O H Wangensteen (*Surg Gynecol and Obstet* February 1932 p 219) points out that the ideal operation for undescended testis is one which will replace and fix it into the scrotum before the onset of those degenerative changes which take place at puberty in such an arrested organ To ensure a good functional result the operation should be undertaken well before puberty, *and preferably* between the ages of 8 and 11 In the adult the only normal site for the testis is in the scrotum since this serves as a thermo-regulating *mechanism* The imperfectly descended testis is *spermatic but before puberty* it resembles *in* every *respect* the *normal* one in the scrotum While the *undescended testis is more likely to* become malignant than the normally descended one *it is in no sense* to be considered as a pre-*cancerous lesion* and testicular malignancy is of infrequent occurrence Wangensteen describes and discusses a method of placing the testis in the scrotum without injury to the testicular blood vessels their adequate mobilization is essential In orchiopexy temporary anchorage in the scrotum is important since without adequate fixation retraction occurs preventing the commensurate growth of the testis The author adds that he has performed this operation with uniformly good results in twenty cases he is satisfied that *protracted* anchorage by approximation of the scrotal skin to that of the thigh is important since only a testis which remains low in the scrotum will develop normal growth

417 Tracheotomy for Oedematous Laryngitis in Scarlet Fever

J D Rolleston and D G Macpherson (*Clin Journ* January *27th* 1932 p 41) record the case of a woman aged *22* admitted to hospital with a mild attack of scarlet fever which became complicated by bilateral cervical adenitis on the sixth day The fauces subsequently became oedematous and on the tenth day she developed urgent dyspnœa so that tracheotomy had to be performed with the patient *in extremis* The tube was removed in two days but much cellulitis and oedema of the neck ensued and ulceration of the tracheal cartilages with perforation of the right lateral wall of the trachea took place Right pleuro-pneumonia developed and 120 c.cm of straw coloured fluid were removed from the right pleural cavity Direct examination of the fluid showed the *presence* of polymorphonuclear leucocytes and a pure growth of *haemolytic* streptococci was found on culture Finally *complete* recovery followed In the authors experience it was unique for mild scarlet fever to be complicated by Ludwig's angina with œdema of the larynx necessitating urgent tracheotomy

418 An Aetiological Factor in *Dupuytren's* Contraction

G Roussy G Lévy and C Rosenbaum (*Ann de Med* January 1932 p *21*) believe that at least a certain type of Dupuytren's contraction is of medullary origin and record a case in support of this view *Clinically* this type is marked by an association *of* the palmar aponeurotic contraction with disturbances of the sensitivity as regards heat or with evident signs of syringomyelia anatomically medullary cavities of *different origins* have been noted in the grey matter Initial signs of the affection are predominance of the ulnar fingers *relative* integrity of the thumb and index finger and prominence of the flexor tendons in the palm and of the tendon of the small palmaris longus in the wrist The appearance of the hand and its pathological alteration resemble that

seen in syringomyelia The constant presence of the syndrome of Claude Bernard Horner and the predominance of symptoms involving the ulnar nerve suggest the existence of lesions in the parts of the cord giving rise to the eighth cervical and first dorsal roots The frequency of vasomotor and trophic troubles with disturbance of the sweat glands and the rare coincidence of contraction of the plantar aponeurosis would indicate involvement of the sympathetic system also The treatment advocated is radiotherapy of the lower cervical and upper dorsal regions of the cord This is contraindicated and specific treatment must be adopted if specific vascular lesions are diagnosed and especially if syphilis is suspected

419 Treatment of Empyema

C A HEDBLOM (*Journ Amer Med Assoc* December 26th 1931 p 1943) classifies empyema as pyogenic (acute or chronic) and tuberculous which is always chronic though there may be no clinical evidence of pulmonary tuberculosis In acute pyogenic empyema the fundamental principle in treatment is complete and early drainage without embarrassment of the respiration or circulation this is maintained until the cavity is obliterated by re expansion of the lung In the early stages of an acute empyema the two pleural cavities function as one Open drainage then lowers the respiratory function of both lungs—a sequel of material import if there is a coincident pneumonia or other toxaemia or the patient is very young or very old The method advocated is closed drainage or aspiration through a rubber catheter and irrigation of the cavity with normal saline or antiseptic solution repeated every two hours during the day and once or twice at night Irrigation is continued until the cavity is obliterated or until there is no further decrease in the size of the cavity In the latter event rib resection and drainage is indicated as also in cases with large bronchial fistulas In chronic pyogenic empyema closed drainage and irrigation with antiseptic fluid is advocated preliminary to operation For large cavities a posterior extra pleural thoracoplasty in two or more stages is the method of choice followed by the removal of the thickened pleura over the residual cavity Open drainage is contraindicated in sterile cases of tuberculous empyema If there is no associated pulmonary tuberculosis the pus is aspirated and filtered air is substituted in such amounts as to keep the pleural pressure at less than the atmospheric tension so that the lung may re expand If there is pulmonary tuberculosis a positive pneumothorax operation and collapse of the affected lung is indicated In both types of cases a plastic operation as for the non tuberculous cases may eventually be necessary

420 Results of Resection in Hirschsprung's Disease

A W FISCHER (*Zentralbl f Chir* January 30th 1932 p 261) discusses the variability in the results of resection of the hypertrophied intestine in Hirschsprung's disease An investigation of the cases operated upon in the Frankfort Clinic in 1927 gives a very gloomy picture of the prognosis The majority of the published figures show that surgical intervention lengthens life by only one or two years The author describes a case in which a total colectomy was performed the lower sigmoid being anastomosed with the ileum Many subsequent observations revealed an increasing dilatation of the lower ileum which gradually surrounded the remainder of the small intestine and also displayed haustration Fischer believes that the formation of a valve where the widened and movable sigmoid joins the fixed rectum is responsible for the great majority of cases of Hirschsprung's disease The bad results of operation especially resection are attributed to the persistence of this valve mechanism which leads to a simple dilatation and hypertrophy of the intestinal wall above it The author concludes that for the successful treatment of the disease a method of resection which removes the valve can alone be considered Valve formation can be obviated and good results obtained by a prolapse method of fixing the pelvic colon

Therapeutics

421 The Possibilities of Renal Opotherapy

S DEJUST DEFIOL and MARIANNE ROMME (*Presse Med* February 13th 1932 p 238) recalling the work of Brown Sequard and Dieulafoy forty years ago pioneers in the use of renal extracts in the treatment of renal disease state that the earlier workers were seeking only for a diuretic action and did not realize that it might be possible to replace artificially a deficient renal secretion Moreover the early extracts caused damage in some cases by the action of protein elements which it is now possible to remove The present authors have used an extract freed from albumin and lipoids and have obtained promising results as regards lowering the blood urea increasing the urinary output and reducing albuminuria The last effect has been more constantly obtained than the increase of urinary output Reduction of arterial tension has been achieved in a number of cases but this result depends on such a variety of factors that they hesitate to regard renal extract as a specific remedy for the condition The diuretic effect has been found to reach a maximum on the third day of treatment a result distinguishing it from treatment with chemical diuretics The authors consider that opotherapy can be divided into two main groups (1) the group including thyroid pituitary suprarenal and pancreatic hormones—isolatable substances having a definite action on a number of bodily systems and capable of being pushed to a point of toxicity and (2) a group comprising renal hepatic and splenic extracts which have a limited action (through unknown substances) only on the corresponding organ and stimulating the natural action without toxic effect In their opinion the action of renal extract in promoting and increasing natural action is more rational than that of chemical substances which only cause a passive diuresis

422 Inhalation Therapy in Pneumonia

Y HENDERSON (*New England Journ of Med* January 28th 1932 p 151) summarizes the reasons for using a mixture of 5 to 7 per cent carbon dioxide and 95 to 93 per cent oxygen (carbogen) in the treatment of pneumonia The deeper breathing which is thus induced prevents the development of occlusion and tends to open up any parts of the lung previously occluded While carbon dioxide is being inhaled morphine or other narcotic drugs may be used more freely to counteract excitement and restlessness and the respiratory stimulus of this gas tends to counteract the depression of breathing which these drugs otherwise induce The solution of carbonic acid which results in the blood is stated to have a bactericidal action on the pneumococcus and a resolving effect on the pneumonic exudate particularly when morphine or other narcotic and respiratory depressant drugs are being administered While carbon dioxide tends to lower the *p*H of the blood and the pneumonic exudate it does not decrease the blood alkali or contribute to the induction of acidosis but rather the reverse The author describes a special tent for the convenient administration of carbogen with a resulting 50 per cent concentration of oxygen this concentration is generally sufficient to overcome cyanosis and is as high as is considered advisable When oxygen alone is used the atmosphere in the tent contains from 1 6 to 2 per cent of carbon dioxide from the patient's breath When 7 per cent carbogen is used the carbon dioxide atmosphere ranges between 4 5 to 5 per cent owing to diffusion to the outside air this amount deepens the breathing but not excessively The temperature under the tent is from 3° to 7° F lower than that of the room and the humidity of the atmosphere is usually from 44 to 57 per cent The windows of the tent are composed of cellophane which is much less inflammable than celluloid they are made large so as to prevent the patient from feeling isolated or imprisoned The author cites animal experiments in support of his contention that this form of treatment is really curative and not merely a way of relieving the symptoms in pneumonia

423 Arsphenamine Treatment of Early Syphilis

A B Cannon and Mary B Kartulis (*Journ Amer Med Assoc* November 21st 1931, p 1521) record a study of the comparative value of arsphenamine, neoarsphenamine, and silver arsphenamine in the treatment of early syphilis in 136 cases. The points especially investigated were the disappearance of visible lesions, reversal of the Wassermann reaction, complications arising from the administration of the different drugs, and the number and nature of relapses. Arsphenamine proved to be the most satisfactory in all respects. The authors state that it involves fewer injections, a smaller dosage, and a shorter time to give a negative Wassermann reaction. Its reactions, immediate and delayed, are slightly fewer than those of neoarsphenamine, and the percentage of relapses is appreciably lower. The effects in the few cases in which the silver salt was tried suggest that it may be more desirable than neoarsphenamine. Both preparations have the advantage of being already neutralized. Silver arsphenamine possesses a lower toxicity than either of the other products, and can often be given to a patient who reacts severely to arsphenamine or neoarsphenamine.

424 Treatment of Experimental Strychnine Poisoning

R J Lyons (*Cronica Medica* January 15th 1932 p 58) finds that intravenous anæsthesia by somnifen (diethylallylisopropyl barbiturate of diethylamine) prevents clonic contraction in dogs given lethal doses of strychnine, and in 88 per cent saves life. Death was due to myocardial paralysis in the remaining 12 per cent, a figure lower than the 14·5 per cent fatality rate in untreated cases. In the primary strychnine clonic contraction are prevented by the administration of therapeutic doses of somnifen. The narcotic action of the drug is localized in the central portion of the spinal reflex arc. The anæsthetic dose to be injected into the dog's intravenously ranges from 0·10 to 0·15 gram per kilo of body weight. Hypodermic injection of morphine or intravenous injection of morphine copalamine, so far from improving the anæsthesia produced by somnifen in the dog considerably increases the toxicity; its use is therefore contraindicated.

425 Treatment of Erysipelas

S Zaffiri (*Riassegna med* January 15th 1932 p 32) has treated forty cases of severe facial erysipelas, of which he records twelve examples in patients aged from 16 to 66, by intramuscular injections of colloidal electric rhodium. The drug proved painless and gave rise to little or no local or general reaction. It was not toxic and did not produce symptoms of intolerance even when its use was continued for some time, nor did it give rise to anaphylaxis.

Neurology and Psychology

426 Chronic Subdural Haematoma

Chronic subdural haematoma is frequently unrecognized although it occurs more often than middle meningeal haemorrhage. A Kallas (*Brain*, December 1931, p 430) reviews eight cases, emphasizes the importance of accurately localizing signs, and maintains that a correct diagnosis of the site of the lesion should invariably be followed by operation and complete recovery. Trauma of the head often trivial is the most important aetiological factor; this displaces the brain antero posteriorly with a resulting tear of one or more cerebral veins as they enter the superior longitudinal sinus, and with subsequent bleeding into the subdural space. A surprisingly long latent period in most cases is best explained on the assumption that there is slow intermittent bleeding into this space. The diagnosis of this condition is based on a history of trauma which after a latent interval is followed by the insidious onset of headache, drowsiness, vomiting, and coma. The most characteristic clinical symptom is a peculiar lethargy alternating from drowsiness to coma with periods of alertness in a few hours or days. Misleading pyramidal tract signs, explainable in one of three ways are frequently noted, and are discussed. A dilated, fixed pupil, on one side even with homolateral paresis or bleeding from the opposite ear indicates the existence of a lesion on the same side. Spontaneous recovery is most unlikely and operation should be performed without delay. This will vary with the patient's condition and the various procedures are described. In seven of the eight cases the lesion was unilateral, and in one it was bilateral. With a unilaterally dilated pupil an opening should be made first on this side; if no pupillary inequality exists a bilateral trephine operation should be performed simultaneously. The two postoperative complications most to be feared are cerebral oedema and extradural haemorrhage.

427 Extramedullary Tumour of the Spinal Cord

In order to illustrate some difficulties in diagnosing spinal tumours G A Preston, M A Stewart and R J Wright Smith (*Melbourne Hosp Clin Reports* December 1931, p 134) record and discuss a case of an extramedullary spinal tumour. In this patient aged 49 the course of the disease was marked by three distinct periods: an insidious irritative onset with pain in the sacral region which gradually involved the lumbar area and was succeeded by root pains—duration 6 months; subsidence of the irritation with no definite evidence of nerve or spinal cord interference—duration 3 months; and a gradually increasing interference with the sensory and motor functions and sphincter control—duration 5 months. These pointed to gradually increasing compression of the cord by the use of lipiodol injections and x-ray films a tumour was located in the lower dorsal region. A laminectomy extending from the eighth thoracic to the first lumbar vertebra was performed and the tumour was excised which proved to be a fibroblastic meningioma. Complete recovery resulted. The nature of the root pains during the early stages warranted investigation of the alimentary and urinary tracts as being possible sites of lesions. The authors remark that spondylitis noted in this patient is not unusual at this age; its nature should however be carefully assessed when confined to a small area since localized spondylitis is frequently indicative of spinal cord tumour. The spinal fluid showed xanthochromia, massive coagulation and normal cell and globulin contents. Such a combination is characteristic of large tumours of the lower thoracic cord the conus medullaris and the cauda equina; excess of globulin without cell increase is most frequently found at other levels. The post operative headache of unusually long duration which occurred in this patient was probably due to leakage of cerebro spinal fluid at the operative site.

428 Torsion Spasm

H G Garland (*Journ Neurol and Psychopathol* January, 1932 p 193) reports a case of torsion spasm (dystonia lenticularis) one of the group of diseases and clinical syndromes which show evidence of striatal dysfunction. His patient was a Jew aged 17 and the case was remarkable in that pyramidal involvement was the first manifestation of the disease. Although there were no involuntary movements in the hemiplegic limbs there was undoubtedly an increase in muscle tone in them at those moments when the trunk was involved in a major spasm. The hemiplegic limbs were wasted, but through out the illness the patient was able to dress himself and could move about the house. At no time was there any sphincter disturbance, loss of consciousness hallucinations visual disorder dysphagia, or deafness. Garland remarks that while this case appears to be typical as regards its Jewish incidence progression and the type of involuntary movements, there was also an associated progressive hemiplegia. The patient showed no signs of cirrhosis of the liver or corneal pigmentation and the possibility of the aetiology being post encephalitic cannot be entirely excluded. The condition certainly seems to be inherited possibly as a Mendelian recessive. In the present case minor involuntary movements of the trunk muscles are at all times to be seen including the abdominal muscles on the hemiplegic side.

Obstetrics and Gynaecology

429 Rectal Gonorrhoea

According to L. BICKEL and L. ABRAHAM (*Zentralbl. f. Gynak.* January 23rd 1932 p. 200) there is a consensus of modern opinion that rectal gonorrhoea in women is almost devoid of signs, subjective or objective. Its frequency in cases of urogenital gonorrhoea has recently been reported as being 10 per cent. to 75 per cent. Such variations are due to varying methods of using the swab to different criteria of bacteriological investigation and to alterations in the proportions of acute cases in various reported series. The authors recommend Glingar's method of examining slides from the particles of mucous membrane derived from a rectal washout with 50–100 c.cm. of lukewarm water. In their view it is essential that the suspected diplococcus should be Gram negative but it need not necessarily be intracellular. Using such criteria they found rectal gonorrhoea in 20 out of 100 out patients suffering from urogenital gonorrhoea including 13 acute cases. Of the 87 chronic cases no fewer than 15 patients had a clinical history placing the infection at least ten years back, and 65 had no gonococci in the cervix or urethra; these chronic cases gave 16 instances of rectal gonorrhoea. The authors ascribe infection of the rectum to the anatomical events of defaecation and to contamination from infected urine. Since purulent rectal discharge is absent in chronic gonorrhoea of the rectum, and since the force of gravity is opposed to the entry of discharge in the vagina, rectal gonorrhoea probably plays little part in causing the chronicity and intractability of gonorrhoea in the female. Nevertheless rectal gonorrhoea affords a source of re-infection of the genitalia by the fingers, toilet paper or instruments.

430 Haemorrhagic Retinitis in Vomiting of Pregnancy

H. J. STANDER (*Surg. Gynecol. and Obstet.* February 1932 p. 129) describes two cases of haemorrhagic retinitis associated with severe vomiting in pregnancy, a complication he believes which has hitherto been unrecorded in the literature. Both patients developed a diffuse haemorrhagic retinitis quite different from the arteriosclerotic type and giving the impression of a diffusion of blood elements through the capillaries due to changes in the permeability of their walls. In the first instance the pregnancy was terminated eight days after the patient first complained of blurred vision but death followed shortly afterwards; the necropsy revealed central necrosis in the liver and necrotic areas in the anterior lobe of the pituitary gland. In the second case which terminated in recovery the pregnancy was brought to an end immediately; blurring of the vision began after lasting for a fortnight the retinitis gradually disappeared. The author has noted similar lesions in the hypophysis in two fatal cases of vomiting of pregnancy, in two of eclampsia, and in one of chronic nephritis during pregnancy. He remarks that while these lesions may have been associated with hyperglycaemia it is conceivable that some toxin may have caused the necroses in the liver and in the pituitary gland. The condition is of grave prognostic significance and is an indication for the immediate termination of the pregnancy. In all patients suffering from severe vomiting in pregnancy repeated examinations of the retina are strongly indicated.

431 Medical Induction of Labour

R. L. DODDS (*Journ. Obstet. and Gynaecol. of the British Empire.* Winter 1931 p. 827) gives a statistical report of 138 cases in which an attempt was made to induce labour medically by the following method. After administration of an ounce and a half of castor oil followed in two hours by an enema and hot bath, 20 grains of quinine sulphate were dissolved in dilute sulphuric acid and given in three two hourly doses of 10, 5 and 5 grains. If labour did not start within eleven hours from the beginning of this course two 0·5 c.cm. injections of pituitary extract were given with an interval between them of one hour. In 63 cases the pains started before the pituitary extract had been given. In 136 cases one course sufficed to induce labour within twenty-four hours after the first dose of quinine, in 43 two courses and in 5 three courses had to be given, so that the total successes numbered 183 or 54 per cent. The proportion of successes was greatest in the post-mature and least in the premature cases; it was greater in patients with albuminuria than in the remaining non-toxaemic group, although this contained fewer premature cases. Those patients requiring second or third courses had some degree of uterine inertia during labour and had a specially high instrumental rate. Stillbirths and neonatal deaths amounted to 14·6 per cent.; the surviving infants showed no special nutritional defects. In about 1·5 per cent. of the labours a stillbirth was possibly but doubtfully attributable to quinine—a proportion which is little different from that of unexplained stillbirths in natural labours. No higher success rate was obtained by giving 50 instead of 20 grains of quinine.

432 The Value of Radiography in Gynaecology

G. COTTE (*La Gynecol.* January 1932 p. 34) discusses the diagnostic value of radiography in gynaecological work under three headings: (1) simple radiological exploration, (2) after the injection of gas into the peritoneal cavity, and (3) after the injection of opaque substances into the uterus. Under the first heading he deals with foreign bodies in the uterus or vagina, calcified uterine myomas and dermoid cysts of the ovary. The third procedure involves the necessity of being alive to the possibility of a ureteral calculus being overlooked. In doubtful cases an opaque sound in the ureter obviates error. The method of rendering apparent the outlines of the pelvic organs by the injection of oxygen or carbon dioxide into the peritoneal cavity is only mentioned to be condemned having been superseded by the third procedure of injecting opaque substances into the uterus and adnexa. Lipiodol (40 per cent.) is stated to be the only substance used for this purpose in France. A sufficient amount should be introduced to allow films to be taken anteriorly and laterally. Accidents with lipiodol are extremely rare. This method has been found of particular use in investigating cases of sterility; obliterations of the passages at any part being made visible. Functional dysmenorrhoea has benefited from a radiological exploration of the uterus. Hydrosalpinx or unilateral sclero-cystic oöphoritis can also be diagnosed thus, and in the investigation of all pelvic tumours such an exploration is most helpful. It reveals at the same time any anomalies of size or shape of the pelvic contents and also the movements of the uterus and tubes.

433 Early Recognition of Cancer of the Uterus

F. EMMERT (*Journ. Amer. Med. Assoc.* December 5th 1931 p. 1684) emphasizes the advisability of detecting a pre-cancerous condition potentially dangerous lesions being cervical tears, erosion, eversion and leucoplakia. This last affection is a disorder of certain mucous membranes characterized by an increased formation of keratin in the superficial layers of the squamous epithelium and a marked hyperplasia of all the other constituents of the mucous membrane until it resembles the epidermis in macroscopical appearance. These changes result in the production of bluish pearly or grayish white plaques which are either level with the surrounding mucosa or slightly raised if the hyperplastic process has been excessive. For the macroscopic recognition of these changes Hinselmann's colposcope is useful. It consists of a pair of binoculars mounted on an adjustable upright stand. The lenses magnify an object from ten to thirty times. By the use of this instrument an unsuspected frequency of leucoplakia was found—namely, in 1 out of 115 patients examined only 10 per cent. were perfectly normal, 10 per cent. had a congenital extension of the epithelium of the cervical canal over the vaginal portion and 80 per cent. showed some degree of erosion. Leucoplakia is most commonly detected in the transitional

zone at the periphery of the erosion A case is reported in which a very early stage of malignant degeneration was recognized by means of the colposcope at a time when there were no symptoms and the usual clinical examination would have failed to arouse any suspicion

434 Diabetes and Pregnancy

C Brecsard (*Nord Mag f Laegevid* January 1932, p 34) records twelve cases in women aged from 22 to 44 in whom pregnancy was complicated by diabetes With the exception of one patient in the pre insulin era all were treated by insulin The total number of pregnancies among the twelve patients was seventeen eight of the seventeen children died (a mortality of 47 per cent) but the only fatal case among the mothers was that in which insulin was not employed Bruns, Gerards and Jacobsen conclusions are as follows The prognosis of diabetes in pregnancy is favourable as regards the mother but bad as regards the child Patients with *mild forms* of diabetes usually pass through their pregnancy without those complications which are liable to occur in severe forms of the disease The patients react well to insulin treatment The course of labour and the puerperal period in diabetic patients show no deviation from the *normal*

Pathology

435 The Significance of the Pituitary Gland in Parturition

H Hitter and P Hoet (*Journ of Physiol* February 8th 1932 p 134) have attempted to decide whether the theory of Dixon and Marshall (who attributed the onset of labour to increase of posterior pituitary hormone in the blood) or that of Bourne and Burn (who postulate a *sensitization* of the uterus by an ovarian hormone to a normal amount of circulating pituitrin) is most nearly correct The experiments of Cow who found that the action of adrenaline in relaxing uterine muscle can be reversed by previous treatment of the muscle by pituitrin have been used as a means of detecting any increase of pituitrin in the blood Bourne and Burn used oestrin which is not protein free Repeating their experiments the present authors also found an increase of sensitization of the uterus to pituitrin but when they employed progynon *which is protein free* this sensitization was not obtained Since also using Cow's adrenaline test a stimulant action was obtained in the case of animals near term they conclude that an actual increase of pituitrin in the blood is responsible for the onset of labour They have also investigated the effect of the proportion of calcium in the saline solution where an experimental uterine preparation is suspended and have found that the effect of pituitrin is increased not in direct proportion to a full in calcium content, but to decrease of its proportion to that of potassium The interior pituitary hormone which is found in the urine of pregnancy also has an effect in enhancing the action of pituitrin Thus the factors leading to onset of labour appear to be an actual increase of pituitrin in the blood together with increased sensitivity of the uterus to its action caused by increase of the K-Ca ratio in the blood and increased secretion of the anterior pituitary hormone

436 A Pathogenic Study of Parasyphilis

In previous experiments on rabbits C Levaditi P Lurine and R Schoen (*C R Soc de Biologie* January 22nd, p 86) demonstrated that after inoculations of *Treponema pallidum* into the cerebrum or spinal canal the virus is not localized in the brain but rapidly leaves the central nervous system to invade the whole organism Since experiments had not yet been performed on animals more akin to the human the authors pursued their investigations on monkeys These confirmed the previous findings and showed that the normal neuraxis constitutes an insuperable barrier to the rapid increase of dermotropic strains of the syphilitic virus Such intra neuraxial increase of the *Treponema pallidum* and the diseases it causes including general paralysis and tabes are only possible under two conditions the progressive creation of strains of syphilitic virus with elective neurotropic affinities and the occasional diminution (transient or permanent) of the natural resistance of the neuraxis to the virus The qualities natural or acquired of the pathogenic agent and of the soil on which it is implanted are of primary importance in determining the aetiological and pathogenic factors of parasyphilis

437 Comparison of the Pirquet and Mantoux Tuberculin Tests

S A Slater and Kathleen Jordan (*Amer Rev Tuberculosis* February 1932 p 218) record the results of an investigation into the comparative value of the Pirquet and Mantoux methods of performing the tuberculin test The work was conducted in a wealthy rural community where living conditions were good the people intelligent and the death rate from tuberculosis during the last five years had been less than 0 25 per 1 000 White school children between the ages of 6 and 18 years were tested schools being selected in the different sized towns and in the country districts so as to afford the best representation of the whole area The Pirquet test was performed by scarifying the skin of the forearm through a drop of undiluted old tuberculin the Mantoux test by injecting 0 1 c.cm of a 1 in 1000 dilution considered as equivalent to 0 1 mg of old tuberculin into the skin of the forearm The two tests were performed simultaneously and the results were read 48 hours later Of a total of 1 006 children tested 105 or 10 4 per cent reacted to the Mantoux and 92 or 9 15 per cent to the Pirquet test Analysing more closely it was found that 42 or 4 2 per cent reacted to the Mantoux but not to the Pirquet procedure while 29 or 2 88 per cent reacted to the Pirquet but not to the Mantoux test 63 or 6 3 per cent reacted to both tests It was observed that the average age of those reacting only to the Mantoux test was 14 years and of those reacting only to the Pirquet test 10 6 years The reason for this difference is not clear but the authors regard it as indicating that the Pirquet test is preferable in the younger and the Mantoux test preferable in the older children On x ray examination of the reactors fifteen children were found with demonstrable tuberculous lesions The proportion of reactors in the whole population was very low being not more than 26 per cent even in persons 18 years old The authors believe that extensive use may be made of the tuberculin test not only to ascertain by further observation the probability of a tuberculin positive child developing clinical tuberculosis but also in country areas where the degree of tuberculization is low of detecting the source of infection among the adult population by examining the families in which positively reacting children are found

438 Evolution of the Renal Syndrome in Amyloisis

M Labbé R Boulin I Bertrand and L Justin Besançon (*Bull et Mem Soc Méd des Hôp de Paris* January 18th p 24) maintain that cases of amyloisis far from having always a pure symptomatology are frequently associated with other clinical manifestations than those of lipoid nephrosis They describe a case of tuberculosis of eight years duration in which the liver was found to be enlarged during two years it passed through three phases In the first there was polyuria accompanied by hypoazoturia in the second simple albuminuria was present with slight temporary oedema and lastly there ensued the azotaemic phase The early appearance of the Congo red reaction which was twice positive was regarded as a danger signal of great importance suggesting amyloid degeneration A little piece of the anterior surface of the liver was removed through a small incision under local anaesthesia this procedure being regarded as safer than the usual trocar method The sections of this piece of liver are described and three drawings are published to show that at least in certain conditions hepatic amyloisis can begin in the interior of the cells themselves and not in the intercellular tissue This is spoken of as a rather late rehabilitation of the anatomical expression "amyloid degeneration

ELASTIC HOSIERY.

The danger of discarding Elastic Hosiery especially nowadays when everyone indulges in various forms of strenuous exercise is obvious to the Medical Man

To eliminate this danger we have produced our famous

DRESS SILK HOSIERY

which is inconspicuous when worn under even the fashionable silk stockings of to day

This Dress Silk hosiery made of the finest woven China Silk with rubber strands is naturally rather more expensive than other weaves and is not suitable for rough wear

Its smooth finish and silky texture however make it eminently suitable for evening wear or for any occasions where a fine stocking is essential

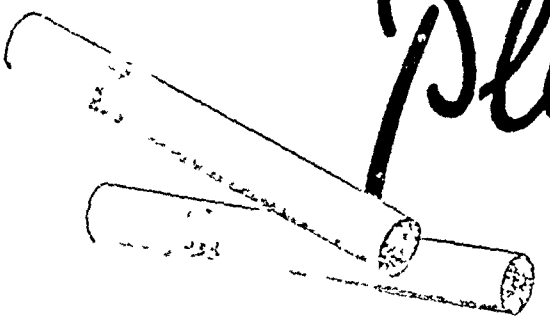
With Triplex Glass and Dunlop Tyres— £298

The "Medico" Coupé

has been specially designed to meet the medical man's needs—it is in fact an outstanding example of what can be done in the matter of adaptation when a car of CLASS not MASS production is concerned. Apart from the fact that it retains all those individualistic features as ocated with Riley productions there are points in its construction which will prove infinitely valuable to the medical profession.



For instance—The two Yale locked Cubby Hole in the dash and a really roomy locker in the rear. This latter also Yale locked and accessible either from the exterior or interior.

It is an ideal two seater—closed or open—and it has a drophead very easily manipulated Triplex screen and windows and—
In a word it is just the car for you. Let us send you fuller details.

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

Extract from the 'British Medical Journal,' Dec. 10th, 1927—

Visceroptosis is the cause of so much discomfort and ill health and an ill fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition Madame Rose has for many years devoted special attention to this problem and we have good reason to believe that she has given help and comfort to a considerable number of sufferers We have received assurances from medical men who have sent patients to her that she gives personal attention to each patient that she takes great care in adapting and adjusting the support to the particular needs of the case

A NON-HABIT-FORMING ELIMINANT

Sal Hepatica possesses all the essential qualities of the perfect purgative Its action is prompt, painless and thorough It is non-habit-forming, because it contains sodium phosphate which increases bile secretion—thereby avoiding the habit-forming propensities of other laxatives that call for steadily increasing doses The exhibition of Sal Hepatica is by far the most pleasant and effective means of eliminating all toxic amino acids from your patient's system and ensuring regular defecation Sal Hepatica *is an efficient eliminant, antacid, cholagogue* and diuretic

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to Bristol Myers Co

Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium

This Registered Hospital is now situated at Monks Orchard in some 250 acres of park pleasure and farm grounds
Applications can be considered on behalf of patients of the educated class in a presumably curable condition
Women new to early treatment voluntary or uncertified patients are admitted
Patients who can contribute 6 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise The Committee will also consider applications for admission at lower rates and in certain cases will be prepared to admit patients free of charge
Every facility for personal investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit In this Unit are found the X ray and Dental Departments and the Bio Chemical Pathological and Psychological Laboratories
Hydro-electric provision is available for Electro Therapy and Hydro Therapy to be carried out in all their forms
In addition to the Resident Medical Staff Consultants in special branches of Medicine and Surgery are available whenever required
The comfort of residential patients is greatly enhanced by the fact that the majority are given single bedrooms
For terms and further particulars apply to the Physician Superintendent at the Hospital

Three vacancies are to be filled. Candidates must be of less than 28 years of age at date of entry (under certain circumstances an allowance for actual service not exceeding six months in respect of a period not exceeding one year as House Surgeon at a Dental Hospital approved by the Admiralty) and must have registered under the Dentists Act as qualified Practitioners. Dental Surgeons in Great Britain and Ireland will be required to appear before a Selection Committee and to pass a professional examination by a Board of Naval Medical Officers as to their physical fitness for entry.

The regulations for entry and the form to be filled up by candidates may be obtained on application to the Medical Director-General of the Navy, Admiralty, London, S.W.1.

The form of application accompanied by the necessary documents must reach the Medical Director-General not later than July 1st.

LEICESTERSHIRE COUNTY COUNCIL.

MEDICAL SUPERINTENDENT

COMBINED COUNTY SANATORIUM AND FEVER HOSPITAL
(180 Beds—120 Tuberculosis and 54 Fever)

The Leicestershire County Council invite applications for the appointment of a Medical Superintendent at their newly erected Combined Sanatorium and Fever Hospital at Markfield from registered Practitioners of not more than 40 years of age who have had extensive practical experience in the diagnosis and treatment of Pulmonary Tuberculosis and also of Infectious Diseases. It is also desired that he should have sound administrative abilities and experience in the training of nurses for examination.

The salary attached to the appointment will be at the rate of £850 per year (together with the use of an uniform) and house (rates and taxes free) with light, coal and laundry, and will rise, subject to satisfactory service by annual increment of £50 to £950. The salary is subject to a temporary reduction of approximately 5 per cent. The foregoing emoluments are valued at £1150 per year.

The gentleman appointed will be required to devote the whole of his time to the duties of his office, and the appointment will be subject to a recent satisfactory medical certificate being provided and to the provisions of the Local Government and Other Officers Superannuation Act 1922.

The candidate appointed will be under the control and supervision of the County Medical Officer, and will be required to furnish such advice and assistance appertaining to his office as may be required.

The appointment will be subject to three months' notice on either side, and the successful candidate will be required to commence duties early in September.

Applications on the prescribed form obtainable from the undersigned, and accompanied by copies of not more than three testimonials, should be addressed to the undersigned, and received not later than Monday, May 23rd.

Canvassing of members of the County Council, either directly or indirectly, will be considered a disqualification.

10 New Street, Leicester. W. J. PEEP, Clerk to the County Council.
April 25th, 1932.

COUNTY BOROUGH OF ROCHDALE

ASSISTANT MEDICAL OFFICER OF HEALTH

The Health Committee invites applications from duly registered Medical Practitioners for the post of Assistant Medical Officer of Health at a salary of £600 rising by annual increments of £25 to £700 per annum, in addition to board and residence at the Infectious Diseases Hospital, and an allowance of £50 per annum for upkeep of motor car (the salary is subject to a temporary economy cut of 8½ per cent).

Candidates must be unmarried, and must be qualified to hold an appointment as Tuberculosis Officer and Venereal Disease Officer in accordance with the Local Government (Qualifications of Medical Officer and Health Visitor) Regulations, 1930, and must possess the Diploma of Public Health.

The successful candidate will work under the direction of the Medical Officer of Health, and will perform such public health duties as may be assigned to him. He will not engage in private practice.

Forms of application may be obtained from the Medical Officer of Health, Public Health Offices, Rochdale, to whom all applications accompanied by copies of three recent testimonials and endorsed "Assistant Medical Officer of Health" should be returned not later than Wednesday, May 18th.

Town Hall, Rochdale. WM. HENRY HICKSON, Town Clerk.

WORCESTERSHIRE COUNTY COUNCIL

ASSISTANT COUNTY MEDICAL OFFICER (Male)

The attention of candidates is drawn to the above appointment, particulars of which were published in the issue of April 23rd, p. 778.

CITY OF PLYMOUTH

RESIDENT MEDICAL OFFICER

Applications are invited from duly qualified medical practitioners for the post of Resident Medical Officer at the City Hospital, Plymouth—a General Hospital of 400 beds.

The person appointed will work under the direction of the Medical Superintendent and will be an assistant to the Public Health Department. Candidates should have had previous experience as House Surgeon or House Physician.

The salary will be at the rate of £3 0 per annum, subject to the usual deduction of superannuation. The appointment is limited to one year, at the end of which time it will terminate, but may be renewed for a further year. Applications, stating age, experience, and qualifications, together with copies of three recent testimonials, should be sent to the Medical Superintendent.

Further particulars may be obtained from the undersigned.

Canvassing, directly or indirectly, will be a disqualification.

Applications, endorsed "Resident Medical Officer," should be delivered to the undersigned not later than Monday, May 16th, 1932.

JOHN SANKEY, M.D., M.R.C.P.H.

Town Hall, Plymouth. Medical Officer of Health.

April 29th, 1932.

CITY OF THE SOKEN

SENIOR ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER

Applications are invited for the above appointments, which will be subject to the Local Government (Superannuation) Acts, 1922 to 1929, and to the Regulations of the Council.

The salary for the former appointment will be £600 per annum, rising by annual increments of £25 to £700 per annum, and for the latter appointment £450 per annum, rising by annual increments of £25 to £500 per annum.

Applicants should be registered medical practitioners, and should have had experience in Public Health work.

Forms of application may be obtained from the undersigned, to whom they should be returned not later than May 14th, 1932.

CHARLES BUTLER, Clerk of the Peace.

County Hall, Spalding.

May 1st, 1932.

PUBLIC HEALTH AND EDUCATION

COUNTY OF THE HOLY TRINITY

Applications are invited for the appointment of Assistant Medical Officer of Health and School Medical Officer for the Holy Trinity Area of the County of Hertford.

The salary will be £450 per annum, rising by annual increments of £25 to £500 per annum.

Applicants must be registered medical practitioners, and should have had experience in Public Health work.

Forms of application may be obtained from the undersigned, to whom they should be returned not later than May 14th, 1932.

CHARLES BUTLER, Clerk of the Peace.

County Hall, Hertford.

May 1st, 1932.

CITY AND COUNTY OF THE CITY OF CHESTER

APPOINTMENT OF MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER

Applications are invited from duly registered practitioners of not more than 40 years of age, possessing qualifications in Medicine, Surgery and Midwifery, experience and training in Public Health for the appointment of Medical Officer of Health and School Medical Officer.

The inclusive salary in respect of the combined appointments will be £800 per annum, rising by annual increments of £50 to a maximum of £1,000 per annum, together with a car allowance of £100 per annum.

Further particulars of the duties, terms and conditions of the appointment and form of application can be obtained on application to the undersigned.

Applications, which must be made on the form provided, are to be endorsed "Medical Officer of Health," and delivered to the undersigned not later than May 30th.

Canvassing, directly or indirectly, will be a disqualification.

THE HOSPITAL FOR SICK CHILDREN
Great Ormond Street, London, W.C.1

A PART-TIME JUNIOR CASUALTY OFFICER is required on July 9th to assist in the Casualty Department from 10 a.m. to 3 p.m. (Saturdays 10 a.m. to 1 p.m.) and to the duties of the Casualty Officer.

The work of this officer includes a large number of tonsillectomies and other minor operations.

Candidates must be registered Medical Practitioners and have held a resident Hospital appointment.

Gentlemen are invited to send in their applications addressed to the Secretary, before 12 o'clock on Monday, May 30th, accompanied by not more than three testimonials, which will be returned to the writers.

The appointment is made for six months and is non-resident.

Salary at the rate of £150 per annum with lunch.

All candidates must be in attendance to appear before the Joint Committee, if required, at their meeting on Wednesday, June 1st, at 5 p.m. precisely.

Forms of application and copies of the rules may be obtained from the Secretary at the Hospital.

By Order of the Board of Management,
JAMES McKAY,
May, 1932. Secretary.

THE HOSPITAL FOR SICK CHILDREN
Great Ormond Street, London, W.C.1

A HOUSE PHYSICIAN and a HOUSE SURGEON are required on July 1st.

Gentlemen are invited to send in their applications addressed to the Secretary, before 12 o'clock on Monday, May 30th, with copies (not more than three) of testimonials, which will be returned to the writers, and at which time they will be required to attend personally before the Board.

The appointments are made for six months. Salaries at the rate of £100 per annum, washing allowance £5, and residence in the Hospital.

Candidates must be unmarried and possess a legal qualification to practise.

All candidates must be in attendance to appear before the Joint Committee, if required, at their Meeting on Wednesday, June 1st, at 5 p.m. precisely.

Forms of application and copies of the rules may be obtained from the Secretary.

By Order of the Board of Management,
JAMES McKAY,
May, 1932. Secretary.

WESTON SUPER MARE GENERAL HOSPITAL (80 Beds)

HOUSE SURGEON

Applications are invited for the post of RESIDENT HOUSE SURGEON at this Hospital. Salary at the rate of £150 per annum with board, rooms and laundry. Duties to commence July 1st next.

Applications, stating age and qualifications, and enclosing copies of testimonials, should be addressed to the undersigned.

JESSE J. HERSTAND,
Secretary.

All communications to be addressed to Mr. A. V. STOREY, General Manager

Before the Operation and After

In preparation for the operation  one tablespoonful of Agarol on retiring  in place of the usual castor oil, will insure against gastric upset.  Again, a few days later  when the patient begins to take nourishment  Agarol in half doses  is the logical eliminant because it stimulates peristalsis  gently without griping or pain.

AGAROL Brand Compound is the original mineral oil and agar-agar emulsion with phenolphthalein It softens the intestinal contents and gently stimulates peristalsis

Agarol Brand Compound is palatable without artificial flavouring and easy to take The usual dose in chronic constipation is a tablespoonful, reduced as improvement takes place

A supply gladly sent for trial.

AGAROL *for Constipation*

In the Light of Modern Knowledge

it has been found that Phlegmonous Processes are best treated by an appropriate application of Moist Heat, which not only affords grateful relief, but often brings about resolution without the necessity for surgical interference.

Antiphlogistine Dressing, due to its osmotic action, to the antiseptic effects of its contents, and to its ability to maintain moist heat for a long time, promotes an active hyperaemia, with absence of irritation, thus hastening resolution and relieving pain.

Demy 8vo 20s net, postage 9d Volume II will be published shortly

A SHORT PRACTICE OF SURGERY

By

HAMILTON BAILEY, F R C S Eng, Surgeon, Royal Northern Hospital, London, etc

and

R J McNEILL LOVE, M S Lond, F R C S Eng, Surgeon Royal Northern Hospital, London, etc

EXTRACT FROM PREFACE —

In presenting this survey of general surgery we have endeavoured to include only such material as is recent or which has been generally accepted Both of us have been engaged in teaching for many years and we have adopted our respective methods in the sections for which we are individually responsible

It will be noticed that two sizes of type have been employed Comparatively advanced surgery and the rarer conditions together with relatively less important matter, have been relegated to the smaller type In this way we have endeavoured to facilitate the assimilation of essentials

Volume II which concludes this work is in active preparation and it is our earnest hope that the reader will find the perusal of the treatise profitable

CELLANBAND PASTE BANDAGES

They are Antiseptic Paste Impregnated, according to the Formula mentioned in the "B M J", October 4th 1930

They exercise a marked dehydrating and antiphlogistic effect, leading to rapid reduction of Oedema

They are vastly superior to Crepe or Rubber Bandages, Elastic Hosiery, etc.

They enable the convalescent to resume reasonable light duties at an earlier period than in the past

CELLANBAND Bandages measure 7 yards, thus affording ample length to provide the 'Heelcap' and "Stirrup' Pieces the application of which before winding so greatly increases the supporting power of the Bandage itself

BED DAMPNESS BANISHED

A Bed is often overlooked as a source of danger to health In our fickle climate, there is need of care in ensuring freedom from bed dampness

Thermega Electric Blankets and Pads are made for this specific purpose

Laid flat on the bed and switched on an hour before retiring the Blanket airs and warms the bed to body temperature The Pad ensures LOCAL regulated heat which may be maintained as long as desired

Both are controlled by an ordinary wall switch (any voltage, 100—250), overheating is eliminated by special thermostatic control, current costs less than a farthing an hour

Blankets from £3 3s, Pads from 31/6d, Heating Blankets for Doctors' couches from £7 Special appliances for pneumonia, operations, etc, to order

Further details supplied immediately on request

"LACTOGEN"

BETTER MILK FOR BABIES

FAULTY METABOLISM

When metabolism is the conversion of food into vital energy, certain waste products are formed. Elimination of these acid and alkaline bodies through the urine and bowels is necessary. Constipation, recurrent migraine, biliousness, etc., are caused by faulty elimination.

Salvitae increases the alkalinity and the solvent power of the blood, prevents the over production of toxins, restores normal intestinal movement, the elimination of effete matter, invigorates capillary circulation, stimulates renal activity, promotes urinary secretion, disposes of uric acid and creates a state of general well being.

VICHY-CÉLESTINS

The world-renowned NATURAL Mineral Water

FERMENTATIVE DYSPEPSIA

When the secretion is vitiated in quality, and the motricity of the stomach weakens that organ dilates and the gastric stagnation allows the micro-organisms of many ferments to develop Quite a series of acids are then to be met with (butyric, lactic, acetic, etc) which not only irritate the mucosa, but further, after their passage into the intestine, become absorbed by the lymphatics and swept into the circulation Vichy-Celestins, by its slightly stimulating action, clears out the stomach and this avoids stagnation and consequent fermentation As, in addition to doing this it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition

CAUTION —Each bottle from the STATE SPRINGS bears a neck label with the word VICHY-ETAT and the name of the SOLE AGENTS

TRADE **PYRIDIUM** MARK

THE IDEAL URINARY ANTISEPTIC

In the treatment of urinary infections, Pyridium (phenyl-azo alpha alpha diamino pyridine hydrochloride) is particularly effective, exercising as it does a powerful antibacterial action against invading organisms particularly gonococci, staphylococci, streptococci and B coli com Pyridium is early and gradually eliminated through the urinary tract in sufficient concentration to exert a continuous antiseptic effect, and in its elimination it penetrates the tissues, thus exerting its bacteriostatic action where most needed It is non toxic in therapeutic doses and is in no way irritating but on the contrary has a soothing effect and stimulates the proliferation of epithelial cells Pyridium is effective in either acid or alkaline urine and is conveniently administered by mouth in the form of coated tablets (0 1 gm) in tins

Fuller information—including technique of treatment—and samples for clinical trial will be gladly sent to any registered medical practitioner, on request

MENLEY & JAMES LTD, 64, HATTON GARDEN, LONDON, EC

. . . the treatment of

ONYCHIA and PARONYCHIA

Practitioners are invited to apply for particulars and clinical sample to the manufacturers

In certain industries, as has been recently emphasised in the medical press, occupational diseases of the finger-nails are extremely common Such diseases are usually most intractable owing to the fact that the organisms involved are deep-seated It has been found, however, that MONSOL LIQUID GERMICIDE, with its bland, but deeply penetrative action, is more effective than any other treatment, and either at full strength or at a dilution of 1-5 will clear up these conditions when all other treatment fails

"Eucortone"

(Extract of Suprarenal Cortex)

In the treatment of

Addison's Disease

Efficacy established by biological tests and clinical use

(*Journal of Physiology* June 6, 1931 *Proc. Physiol. Soc.* May 2, pp 4 5, and 9)

"Eucortone" is prepared by the method of Swingle and Pfiffner, and is highly successful in the treatment of Addison's Disease Particularly striking is the rapid restoration of appetite, weight, strength, and feeling of well being Biological tests and clinical use show that "Eucortone" contains the long sought cortical hormone in an active *state and is free from adrenalin activity The extract contains no* irritant or toxic substance, and is sterile

1 c cm is equivalent to 30 grams of cortex In rubber capped bottles of 25 c cm.

Diabetic Rusks

"Allenburys" Diabetic Rusks are the latest addition to a gradually increasing series of preparations specially designed for patients who suffer from diabetes mellitus or a tendency to obesity These rusks are sugar free and have approximately the following content of calorific materials

Protein	56 0%
Carbohydrate	22 5%
Fat	6 5%

Their calorific value is 10[illegible] calories per ounce and the average weight of each rusk is two fifths of an ounce

'Allenburys Diabetic Rusks have been issued only after prolonged investigation as to the best method of manufacture in order to obtain rusks that while sugar free and of low carbohydrate content should be palatable and should take on an attractive colour from the toasting process They are crisp have a distinctive flavour and provide a welcome change for patients on restricted carbohydrate diets

When you suspect PARTIAL Deficiency of Vitamin B prescribe 'BEMAX' the richest natural Vitamin B food.

The importance of chronic Vitamin B deficiency in the nutritional picture becomes more apparent every day Its signs seem to be a progressive impairment of gastro-intestinal function with anorexia, nervous debility and general weakness It may be suspected in every case of Dyspepsia, Sleeplessness Intestinal Stasis with Constipation Rheumatism, and all nervous complaints

BEMAX affords a simple, pleasant way of restoring a balanced metabolism by providing the necessary quantity of Vitamin B, together with Vitamins A, E, and valuable mineral salts

BEMAX has only a very low roughage content (1.5%) and low starch content It contains at least 500 units of Vitamin B (complex) per ounce (Sherman method) It is delicious, convenient and economical food

Laboratory reports on BEMAX and a full size carton for clinical trial will be sent to any practitioner on receipt of his professional card

THE BEMAX LABORATORIES, 23, UPPER MALL W 6

'ZYMINE' Peptonising Tubes

(FAIRCHILD)

For the preparation of Peptonised Milk and other Predigested Food for the Sick.

'Zymine' Peptonising Tubes have been in use since 1882 making it possible for physicians to assure proper nutrition to their patients even in cases where digestive power has been reduced to its lowest terms and enabling chronic dyspeptics, invalids, convalescents etc., who must live upon fluid foods for more or less prolonged periods, to take milk in quantities sufficient to maintain nutrition and promote restoration

PEPTONISED MILK presents all the nourishment of plain milk freed from the objectionable qualities which constitute so serious a drawback to the utilisation of milk in the feeding of the sick. And of the many methods employed to make milk available food for the sick, there is none that approaches the 'Fairchild' peptonising process in the certainty with which it accomplishes the desired purpose.

Supplied in boxes containing 6 and 12 Tubes

The contents of one tube will peptonise one pint of milk

B.D.H. VITAMIN PRODUCTS

4 in 1

AVOLEUM is a highly active solution in oil of purified Vitamin A without the admixture of Vitamin D It is standardised to a Vitamin A activity equivalent to 120 times that of good cod liver oil AVOLEUM is administered in septic conditions where intensive treatment is necessary and for the purpose of aborting the common cold or overcoming infection in influenza pneumonia and similar acute conditions It is especially suitable for middle aged and elderly patients and for other cases in which the calcifying Vitamin D is contra indicated

RADIOSTOL — the original British irradiated ergosterol solution employed in medical practice—is the product used as a source of Vitamin D in the experimental work on the functions of this vitamin RADIOSTOL is a specific for rickets infantile tetany and faulty calcification generally Originally RADIOSTOL was the total product of the irradiation of ergosterol but now as a result of later investigations by workers at the National Institute of Medical Research it is isolated from this total product in the form of pure crystals of Vitamin D — known by the name Calciferol RADIOSTOL (Calciferol B D H) possesses an unvarying degree of Vitamin D activity of 40 000 antirachitic units per milligram and RADIOSTOL SOLUTION is standardised to an activity of 50 times that of good cod liver oil

RADIOSTOLEUM possesses Vitamin D activity equal to that of RADIOSTOL SOLUTION Its source of Vitamin D is pure crystals of RADIOSTOL (Calciferol B D H) It is standardised by chemical physical and physiological methods to a Vitamin A activity equivalent to 60 times that of good cod liver oil RADIOSTOLEUM CAPSULES are equal in Vitamin A activity to 120 times the same volume of good cod liver oil one capsule being equivalent to three quarters of a fluid ounce of good cod liver oil

It was through the medium of RADIOSTOLEUM that the anti-infective properties of Vitamin A were discovered and now RADIOSTOLEUM administration finds a wide sphere of usefulness in preventive medicine particularly in the pre natal period and during lactation It builds up the mother's resistance against infection and reduces the tendency to dental caries it ensures also correct skeletal development in the child

RADIO-MALT contains RADIOSTOLEUM (Vitamins A and D) and in addition standardised quantities of Vitamin B_1 and B_2 RADIO MALT is now so widely prescribed that it may be assumed that its remarkable tonic properties are known to medical practitioners everywhere

SANITARY TOWELS

The careless attitude of women of all classes towards the hygiene of menstruation is so generally known, and deplored, by the medical profession that any lay comment would be out of place

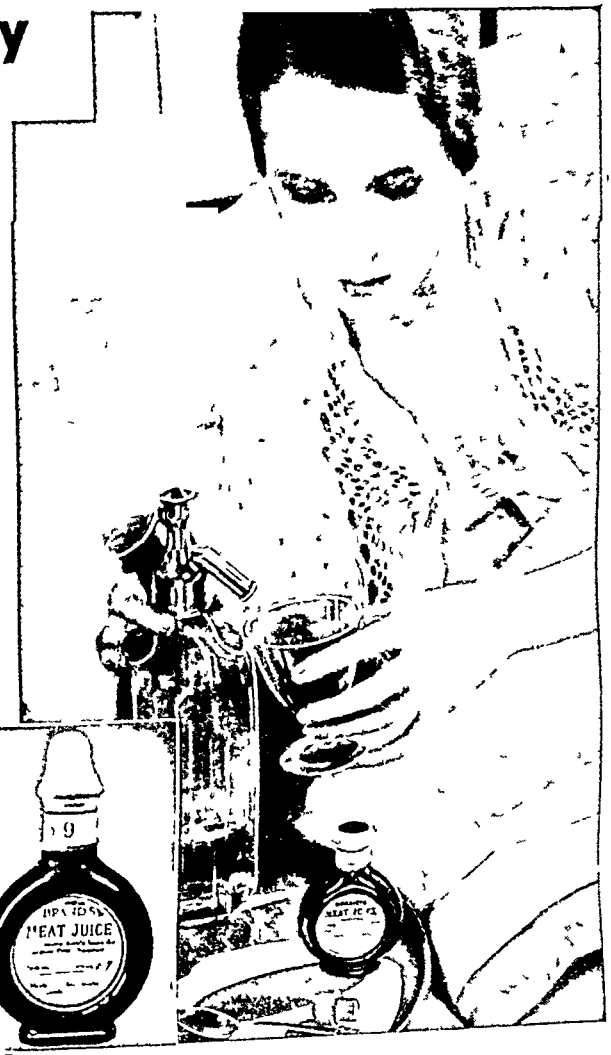
But in the presence of figures proving that four out of five menstruating women still use the old fashioned home-made washable towels which have so long been condemned as insanitary

WE WOULD RESPECTFULLY DRAW THE ATTENTION of the Profession to the fact that there is a British Sanitary Towel on the market which conforms to the highest possible standards of cleanliness *These towels can be bought so cheaply that there is no woman, short of the actually destitute classes, who cannot now afford to discard old-fashioned habits and use nothing but the best, modern SANITARY towels*

One point, in special favour of these towels, is that their absorbency is such that the misery of chafing is unknown to their wearers

THIS ANNOUNCEMENT is inserted by the makers of Lilia — the British Soluble Sanitary Towel They invite comment and enquiry from all interested members of the medical profession, and will welcome every kind of investigation Samples of Lilia towels will gladly be sent They will also be pleased to send you copies of a little medical handbook which, in an earnest endeavour to propagate enlightened habits of feminine hygiene among women of all classes, is being distributed as widely as possible among the women of the country The booklet, which is a simple treatise on the hygiene of menstruation phrased in everyday language, is written by a Woman Doctor whose services the manufacturers of Lilia retain in an advisory capacity

Sashena Ltd. *Paragon Works, Hull*



(An associate company of the Kotex Co. Ltd.)

So many doctors from all parts of the country—indeed, all parts of the world—wrote us for information regarding the above announcement when it appeared in the March 12th issue of the "British Medical Journal" that we are repeating it for the special benefit of those who may have missed that opportunity

BRAND'S Meat Juice and Calf's Foot Jelly

—with palatability quite equal to the famous

Brand's Essences

ANALYSIS proves this *British* meat juice far above foreign meat juices in coagulable protein content—and patients find it really delicious to taste It is prepared with the utmost care by Brand & Co , makers of the famous Essences of Chicken or Beef—*yet it actually costs less* than foreign meat juices

As with meat juice, so with Brand's Calf's Foot Jelly, Brand's Essences of Chicken or Beef, Brand's Real Turtle Soups, Turtle Jellies, Invalid Soups, etc Whenever palatability has to be studied in arranging a patient's diet medical men find these attractive invalid foods quickly rouse appetite All Brand's foods are sterilized

A Lecture

VASOVAGAL SYNCOPE AND THE CAROTID SINUS MECHANISM

WITH COMMENTS ON GOWERS'S AND NOTHNAGEL'S SYNDROME

BY

SIR THOMAS LEWIS, M.D., F.R.C.P., F.R.S.

(From the Department of Clinical Research, University College Hospital, London)

In the present article a form of fainting is described for which the term vasovagal syncope will be found most appropriate. It forms a common and interesting disturbance of a transient kind. It will be described and discussed in relation to a mechanism that has been under close investigation in recent years. There is another and distinct condition with which terminology tends to confuse it—namely, what I shall call for convenience Gowers's syndrome; there is also a third condition probably comprising a vasomotor disturbance—namely, Nothnagel's syndrome, and thought by some to be identical with Gowers's syndrome. The available evidence relating to these last two maladies will be considered sufficiently to allow us to see what there is in it of significance from the standpoint of the vascular system.

VASOVAGAL SYNCOPE

Thirteen years ago I became interested in what may be called common fainting attacks, or more precisely vasovagal syncope. Such attacks had long been known, but although many essays were written in the eighteenth and nineteenth centuries upon syncope, actually it was not until the analysis of disordered action of the heart-beat was accomplished that a real basis for differentiating between forms of syncope trivial and grave was found. I have previously indicated the belief that that very active phase of clinical work during which cardiac irregularities were sorted out meant far more to medical progress than the mere analysis of disordered action of the heart-beat. It brought with it a sharpened and more real point of view, clear recognition that much of what had stood for knowledge in medicine was hypothesis based on slender foundations, and a more insistent demand that reasoning from ascertained facts should replace speculation. Syncope may be cited as an illustration of this changed outlook. Graphic methods of studying the heart's mechanism soon enabled type of syncope due to disordered action of the heart to be divided off and because these became well defined in the process they were divided off with finality. Other and common or types were for the moment left where they were, but not without its becoming manifest by contrast that their nature was almost unknown. Although the form of syncope of which I shall speak was widely recognized as a thing apart it had received no study. The very simplest facts necessary to its correlation and description, such facts as the change in appearance, could be presented were practically unknown, and [illegible] recent it remained undefined and its essential nature could not be recognized. It [illegible] that if patients were to be studied who were subject to these fainting attacks and their circumstances during them [illegible] objects by Cohnheim and by [illegible] been [illegible]

[illegible]

[illegible]

[

Of syncope occurring as it well known it may in response to pain I speak a little more diffidently but I have strong reason to suspect that syncope during the painful phase of coronary thrombosis during the manipulation of diseased joints in gallstone colic and in renal colic is of the kind discussed but in the case of most of the different observations have not been made as yet positively to identify the form of syncope they should be made and that is chiefly why I am instancing them

Phenomena of the Attack

The description of the attacks may begin with an actual example others will be found in our original report

A soldier aged 21 was invalided from active service From his shoulders until the time when he was seen he had been unable to play strenuous games owing to breathlessness and the early onset of exhaustion He was invalided for the symptoms of became he had fainted while on guard duty when attempting to salute an officer of high rank of whom he became aware abruptly He was an undersized and poorly developed man presenting no clear signs of disease in heart or other organs On December 18th 1916 the patient was sitting and a few cubic centimetres of blood had been withdrawn from a vein in the arm and the needle removed He was watching the operation and began to feel queer as though his stomach had turned upside down he complained of dizziness facial pallor was noticed and he head fell forward to his knees He was placed at once on a long cane chair and further observed He then turn the pallor was intense and he was in the The pulse was imperceptible the heart sounds distant its rate 60 beats being 50 per minute the action was for the most part regular a single premature beat being heard From time to time there were retching movements The pupils were little if at all dilated The patient was limp mentally confused or actually unconscious for several minutes a heavy sweat broke out over his forehead pending over chest and body the pallor remained extreme Respiration was slow and sighing The pulse was imperceptible for several minutes as it returned the systolic blood pressure was registered at 60 mm a little later the pressure fell to 55 then to 50 the pulse rate varied between 50 and 60 One minute after the onset some recovery was observed the pulse rate had risen to 64 and the blood pressure to 80 Nine minutes after the onset the patient was able to respond to questions The pulse rate was 88 and the blood pressure 105 the blood pressure gradually rose to 110 Half an hour later he was able to leave the chair and walk unsupported across the room He was tremulous and tired for thirty six hours subsequently His average blood pressure in ordinary circumstances was 118 and the pulse rate 80 to 90

To generalize the central feature of the attack is the syncope In some cases the loss of consciousness occurs without warning of any kind and may then result in a heavy fall and injury More usually the subject is aware that fainting is imminent and sits or lies down deliberately or slips or falls more slowly and involuntarily to the ground [illegible] warning consists of a feeling of instability [illegible] humming of vision and a feeling of [illegible] over my sense of rotation or of [illegible] before the eyes often a very [illegible] entrating auditory vertigo The [illegible] ever while the subject is lying [illegible] n the history is often crucial in [illegible] l from major attacks of cardiac [illegible] standing or sitting position is [illegible] r and frequent form of giddiness [illegible] to syncope which is due to a [illegible] is characteristic of this giddiness [illegible] d to the act of rising to the erect [illegible] pe here described there may be [illegible] hair feeling in the abdomen some [illegible] CAUSE [illegible] t experienced in falling rapidly in chill or in association with nervousness it is generally accompanied by nausea sometimes by retching sometimes by the feeling that the bowels will be moved shortly

In uncomplicated cases I have not known patients to speak of precordial distress or constriction or of any real alarm The symptoms that have been discussed all belong to the attack, to describe them as premonitory is merely to say that they occur before consciousness is actually lost, the cardiovascular changes leading up to loss of consciousness have already begun From the start there is a progressive lowering of blood pressure and almost always a steep fall of heart rate the pulse usually becoming imperceptible and the heart rate falling to 50 or 40 (unusually to 30 or 20) beats per minute Pallor accompanies this fall of blood pressure increasing in intensity it ultimately becomes extreme in the face but is absent or much less evident in dependent parts such as the hands This pallor is of the type associated with simple drainage of blood from the skin to dilating visceral vessels The cerebral manifestations indicate the degree and duration of cerebral anæmia and from the standpoint of the circulation are to be regarded as incidental When the circulatory changes happen gradually syncope is led up to by feelings of insecurity and dimness of vision objectively by incoordination confusion of speech restlessness yawning and decreasing response to questions and to physical stimuli actual loss of consciousness with flaccidity ' If the changes are sufficiently pro found the [illegible] al reflex vanishes there may be slight clonic [illegible] the face upper limb and trunk The tongue is not bitten nor is the urine passed In the severer attack respirations are slow deep and sighing sweating is almost invariable breaking out on lips and forehead or over the body generally usually free it sometimes drenches the clothing

Recovery is invariable and is generally slower than is the onset in it the patient is limp and inert and the skin is pale and wet The attack is almost always brief lasting usually from two to ten minutes occasionally longer it leaves the patient tremulous weak and sometimes with severe headache these after effects are usually brief but may last for hours A large quantity of watery urine is often passed after the attack

Cause of the Syncope

The slow pulse in the attack is due as has been shown polygraphically to a slowing of the whole heart irregularity a common feature of vagal slowing is often displayed The proof that slowing is vagal is given by atropine which promptly drives the rate to levels usual under atropine

The slowing of the heart to 50 or 40 exceptionally to 30 beats per minute is insufficient to induce unconsciousness such rates are frequently seen in cases of heart block that are without symptoms The idea that because the vagus is responsible for the slowing the force of ventricular contractions will be weakened is open to serious doubt Appreciable weakening of the beats from this cause has not been demonstrated in mammals in the dog the heart rate may be reduced to one half by vagal stimulation without altering the mean blood pressure materially Undoubtedly the main cause of the fall of blood pressure in these attacks and the enfeeblement or loss of pulse is independent of the vagus and lies in the blood vessels Atropine while raising the pulse rate up to and beyond normal levels during the attack leaves the blood pressure below normal and the patient still pale and not fully conscious Attacks in which the blood pressure sinks without a lowering of pulse rate and the patient verges on unconsciousness whenever the pressure reaches certain low levels have been encountered Thus

the cause of syncope is rarely a cardiac lesion but the vagus additional to the clinical picture by inducing convulsions absence of heart beat manifestation. The combination of cardiac vascular effect will fully justify the attention to the consideration of the views which possibly very relevant to the pathology of the cases discussed.

Carotid Sinus Reflex

In recent years a very great deal of interest has been aroused in a mechanism connected with what is now called the sinus carotidicus. This mechanism has been shown to exercise a powerful controlling influence upon heart rate blood pressure and respiration and especially in regulating the circulation to the brain. A rise of pressure within the carotid sinus results in a reflex lowering of heart rate and of systemic pressure the former is produced through the vagus and the latter through vasomotor nervous channels (Hering)[2] and through an effect on suprarenal secretion (Hermans)[3].

This important discovery has come to us originally as so many have through clinical observations. Hering is in the true sense of the word the discoverer in that his careful and prolonged researches first gave proof that a special mechanism exists and located it. Hering was led to this investigation during the period when he was carrying out his important clinical observations upon patients suffering from irregularity of the heart. He was struck by the lightness of pressure upon the carotid sheath near the bifurcation of the artery that sometimes suffices to produce slowing of the heart rate and it seemed to him improbable that the latter could result from stimulation of the vagus. The fact that pressure upon the carotid region of the neck will slow the heart had of course been known for many years previously and such pressure has often been referred to though incorrectly as Czermak's experiment[4]. This physiologist published his observations upon pulse slowing in 1866 both he and Waller[5] whose publications came four years earlier attributed the effect to stimulation of the vagus nerve. But the original observation is neither Waller's nor Czermak's but is Parry's. This Welshman famous as clinician and experimenter wrote in 1799[6] as follows:

In patients whose hearts have been beating with great quickness and force I have often in a few seconds stopped their motion many pulsations in a minute by pressing on one of the carotid arteries. An instance of this kind occurred in the case of the late Admiral X. His pulse was quick and already very full and tense. Pressure on one carotid almost instantly reduced the pulse from sixty to forty beats in a minute without having previously altered either its frequency or strength. The latter returned to its former state as soon as the pressure was removed.

The carotid artery contains the receptor part of a mechanism the glossopharyngeal nerve conveys the impulse to the medulla but here it produces two effects: influences they inhibit the heart and the blood pressure motor tone. This remarkable and seemingly paradoxical group of reflex cardiovascular effects is associated with the depressor nerve is stimulated (see Bayliss and Hermans and Boeke) that is why depend the [illegible] central parts of the nervous system. As a general [illegible] it is not highly probable that the [illegible] efferent parts of this [illegible] the clinical syndrome of vasovagal [illegible] not vagal effects are known [illegible] vasomotor effects?

[illegible]

anterior pillar of the fauces and there was a malignant ulcer over the bottom of the gingival groove opposite the sites of the molar teeth The mouth could be opened only three quarters of an inch No glands were palpable in the neck X-ray examination showed no evidence of bony involvement He declined treatment by surgery or radium Blood pressure 185/125

Treatment produced no reaction until the dose of pituitrin reached 1 c.cm but when there was pallor coming on about ten minutes after the injection there was at no time any considerable pain reaction After six weeks the ulceration and induration had advanced and the swelling on the outside of the face was more marked enlarged glands were palpable in the left submaxillary region He left hospital after eight weeks but returned treatment elsewhere for a further three weeks The blood pressure had fallen to 175/110 and it continued to fall the lowest point reached being 135/115 At the end of eleven weeks he had a left hemiplegia of cerebral onset thought to be due to thrombosis The growth was larger and approaching the surface of the cheek and the glands in the submaxillary region were larger firm and fixed to the mandible The patient died twelve weeks after starting treatment no post mortem examination was made The total amount of pituitrin given in this case was 214 c.cm and of theelin 27 c.cm

The cause of the cerebral thrombosis could not be ascertained with certainty but the possibility of its being due to lowering of the blood pressure must be entertained He had however sustained a head injury five years previously as a result of which there was a slight weakness on the right side

CASE IV

Epithelioma of Vulva

M M female aged 60 Nine months history of vulval soreness with frequency and difficulty in micturition On the right side of the vulva was an ulcerated and bleeding growth 3 inches by 1 inch extending into both sides of the vestibule There were enlarged glands in both groins Section showed keratinizing squamous celled carcinoma Blood pressure 140/80

Treatment produced some local pain—not sufficient to require the use of a sedative The patient was always constipated The blood pressure fell to 115/65 and the growth gradually increased in size She died after five weeks treatment no post mortem could be held

CASE V

Epithelioma of Vulva

J I female aged 61 History of a lump in the vulva for one year and incision of an abscess in the left groin three weeks before admission On the right labium was an ulcerated mass 3 inches by 1½ inches extending around the posterior commissure to the left labium and internally around the urethral orifice and into the vagina In the left groin was an indurated mass discharging pus and in the right several hard enlarged glands Section showed keratinizing squamous celled carcinoma

Treatment produced a sharp local pain reaction and generalized pallor as the dose was increased the pain became more severe No change took place in the primary growth but the glands in the groin became larger and new secondary glands developed She was discharged home after six weeks treatment having received 59·5 c.cm of pituitrin and 16 c.cm of theelin

In both this and the previous case the growth was readily observable the changes that took place were all in the direction of extension

CASE VI

Carcinoma of Rectum

I K female aged 27 History of nine months constipation with the passage of blood and slime On rectal examination there was a fixed ulcerating carcinoma completely encircling the bowel lumen and extending down to within 2 inches of the anus Laparotomy showed that the upper edge of the ring of rectal growth had already extended to the peritoneum and there were enlarged glands in the mesorectum No other secondary deposits were found The growth was considered inoperable and a left inguinal colostomy was performed

Treatment produced considerable local pain reaction and pallor After six weeks the growth was larger on rectal examination its lower margin reaching to within 1 inch of the anus Treatment was stopped on account of the very poor general condition

CASE VII

Carcinoma of Rectum

M I female aged 27 Six months before treatment started she came to hospital on account of constipation pain in the left lower abdomen, and frequency of micturition There was a mass rising from the pelvis into the left side of the abdomen and on rectal examination this was felt as an indefinite mass in the posterior and left wall of the rectum extending in front to within 2 inches of the anus There was evidence of a vesico-rectal fistula *Left inguinal* colostomy was performed the growth was felt to be spreading between the layers of the left broad ligament and was deemed inoperable After colostomy she improved at first put on weight and lost her urinary symptoms but she returned in six months with increasing pain in the back The growth had increased slightly in size Blood pressure 108/80

Treatment caused at first a severe local pain reaction even with a dose of only 0·5 c.cm of pituitrin Later on with larger doses the pain was not so severe (it was thought to be worse when no theelin was given) finally there was no pain after the injection The colostomy acted fairly regularly about twenty minutes after an injection and there was considerable haemorrhage from the rectum which diminished if the injection was omitted for a few days After six weeks treatment spread over a period of nine weeks with intervals the mass could still be felt in the left lower abdominal quadrant By rectum could be felt a fungating carcinoma extending around the whole circumference of the rectum In front it reached to within about 1½ inches of the anus and was fixed to the recto-vaginal septum behind it reached about 3 inches from the anus and was fixed to the sacrum Considerable haemorrhage followed examination There was X-ray evidence of secondary new growth in the sacrum probably by direct extension Blood pressure 100/70 This patient still felt that the injections were doing her good and was anxious to continue them although the growth had become larger

Cases VI and VII were two rather similar examples of carcinoma of the rectum in young women The growth continued to extend under treatment in each case although there was in *Case VII* some evidence of more rapid breakdown in the centre with resulting haemorrhage and extrusion of small sloughs

CASE VIII

Secondary Carcinoma of Mesenteric Glands

C B male aged 86 Nine years before he had had a colostomy and perineal excision of the rectum for carcinoma Eight years later a mass of glands was excised from the left groin and found to contain secondary columnar celled carcinoma Before starting treatment his condition was as follows the scars in the perineum and groin were healed with no evidence of recurrence above the colostomy opening there was a mass of glands palpable firm not tender moving slightly on respiration and apparently on the course of the inferior mesenteric vessels The colostomy acted regularly twice daily Blood pressure 190/80

Treatment produced some aching round the waist but no definite local pain reaction With a 1 c.cm dose of pituitrin the colostomy acted regularly five to ten minutes after the injection *After eighteen* days treatment the blood pressure was 180/85 After ten weeks treatment the abdominal tumour was unchanged the general condition was not so good and he complained of pain in the lower chest for which no physical signs were found He was getting weaker and treatment was stopped and subsequently he felt more comfortable Four weeks later the abdominal tumour was in *statu quo* Blood pressure 130/60

This was a case of slowly growing carcinoma which had gone for eight years before a recurrence appeared Treatment had no apparent effect on the subsequent course of the disease

CASE IX

Carcinoma of Prostate

F H male aged 64 Six months previously permanent suprapubic drainage had been established elsewhere for carcinoma of the prostate On examination the prostate was moderately enlarged stony hard and nodular and infiltrating the base of the bladder the median sulcus was obliterated X ray of the pelvis showed no definite bony secondaries He complained of considerable pain passing down the backs of both legs and of irritation in the perineum On the personal suggestion of Dr Susman it was decided to give him a short course of treatment with the idea of relieving his pain He was treated for ten days during which time there was *no local pain reaction and no alteration in the amount of* pain he suffered He died eleven weeks after starting treatment Post mortem examination showed the prostate filled with scirrhous carcinoma spreading into the seminal vesicles and pelvic cellular tissue and bony secondaries in the sacrum

Injections of pituitrin up to 2 c cm twice daily with theelin 0 3 c cm had no effect in alleviating the pain

COMMENTS

Except in Case I where there was a local diminution in the oedema of the tongue overlying the growth there was no beneficial effect which could be attributed to the injections of pituitrin and theelin All the cases followed the usual course of the disease for the particular type of growth In no case was life prolonged nor was there regression of any of the growths

PHYSIOLOGICAL EFFECTS OF PROLONGED ADMINISTRATION OF PITUITRIN

The cases described above were investigated from the following points of view blood pressure—immediate and remote effects electrocardiographic changes onset and distribution of pallor and other vessel changes changes in urinary volume and presence or absence of glycosuria and effects on the bowels

Blood Pressure

In most of the cases the immediate effect was to lower the blood pressure the systolic being more affected than the diastolic The extent of the drop varied from nothing up to 50 mm systolic The maximum fall of diastolic pressure was 30 mm

Typical figures were as follows

Initial blood pressure 180/130—injection 2 c cm pituitrin intramuscularly After 5 minutes 175/130 after 10 minutes 160/120 after 15 minutes 150/115 after twenty minutes 150/115 after thirty minutes 145/115 after forty minutes 150/110 after fifty minutes 160/110 after sixty minutes 165/120

In two of the patients a rise of blood pressure was obtained *after the first injection but it was of negli*gible dimensions—in one case from 185/120 to 190/120 and in the other from 130/75 to 135/80 Both these cases on the following days showed a fall of blood pressure similar to that noted above so that the rise obtained on the first occasion was doubtless emotional in origin In those cases in which pituitrin was given for a long period the resting level of the blood pressure showed a tendency to fall It is impossible to say to what extent this fall was due to the low diet the partial rest in bed (very few were entirely confined to bed) or the pituitrin As an example of the extent of the effect it may be mentioned that in one case the blood pressure fell from 190/80 to 130 60 in three months and in another from 160/85 to 140 75 in a month These results differ from those *obtained by* Sacks This worker using doses up to 1 c cm subcutaneously in man found minute rises while doses of 1 40 to 1/20 c cm intravenously produced immediate rises after one to three minutes of 5 to 15 mm systolic pressure

Electrocardiographic Effects

Records were taken before the administration of pituitrin *and at times varying from one minute to forty five minutes* afterwards In most cases lead II only was employed but in some of the later ones all three leads were recorded The records showed very little change as the result of pituitrin administration There was little effect on heart rate *some subjects quickening to the extent of two beats* a minute others slowing to a similar extent There were no changes in rhythm Those graphs which showed any changes had a slight increase in amplitude of all the waves this being most marked in P and T waves but little else was seen There were no ectopic beats Gruber and Kountz using *intravenous* doses of pitressin of a similar amount per kilogram body weight in the dog found marked changes in the shape and rhythm of the curves[3] Goldenberg and Rothberger[4] also obtained marked electrocardiographic changes in animals given intravenous injections These they attribute to constriction of the coronary arteries by pitressin The absence of such changes in our records even after doses of 4 c cm may be due to the different route of administration and the slower absorp*tion into the circulation*

Changes in Skin Vessels

Pallor came on very soon after the injections in all cases It took about five to ten minutes to develop and lasted twenty to thirty minutes It was not found that the latent period of development or the duration of the pallor was altered in any way during the course of the investigations Pallor was most marked in the face nose and ears but was distinct in the skin of the arms and trunk In several subjects it was noticed that between the injections the blush area on the face and nose was a good pink colour thus giving the patient a very deceptive air of well being This was not due to any increase of haemoglobin as was shown by blood counts and by the anaemic appearance of the mucous membranes It was thought that the flush was due to dilatation of the skin vessels in this area of a paralytic nature following the repeated firm constriction

Urinary Volume

It is well known that intramuscular injection of pituitrin in the normal subject has an anti-diuretic effect[5] In these investigations a decrease in the volume of urine excreted though not to the extent expected from the effects seen on normal subjects was observed This effect was not maintained as the treatment progressed This is in accord with the diminution in effect of a given dose of pituitrin noticed in subjects with diabetes insipidus In two cases faint traces of sugar appeared in the urine at the beginning of treatment but this disappeared later It must be remembered in this connexion that the patients were on a Beaumont and Dodds diabetic diet XI * and this would counteract any tendency to glycosuria In one case though 2 c cm of pituitrin were given twice daily the urinary volume was 40 ounces or less on only five days out of thirty In another case the urinary volume on 2 c cm twice daily was less than 40 ounces on seventeen occasions out of twenty two and on reduction of the dose to 1 c cm twice daily it was below 40 ounces on three occasions out of fifteen The urine was never concentrated to a specific gravity of more than 1020

Bowels

The effect on the bowels was surprisingly slight. Only two patients both with colostomy showed stimulation of bowel movement In both an evacuation occurred

* The contents of carbohydrate 54 grams protein 106 grams fat 114 9 grams—total calories 1 679

ten to twenty minutes after each injection The other patients were confined in spite of the injections, and required the same dose of aperients during as before treatment Those patients having normal evacuation were unaffected by the treatment Only one patient complained of transient abdominal griping following the injections but the reaction was inconstant

We are indebted to Mr Victor Bonney and Mr A T Webb Johnson for permission to treat and observe some of their cases and to Dr Stanley White of Messrs Parke Davis and Co for generous supplies of pituitrin and theelin The urine analyses were carried out in the Courtauld Institute of Biochemistry Middlesex Hospital Lieut Colonel J M Weddell R A M C kindly continued the treatment in one case and allowed us to see the patient subsequently

SEPTIC FOCI AND NORMAL LABOUR

BY

HELEN LLEWELYN M D

Though it is not always easy to say what constitutes a normal labour no one could deny that some of the cases met with in the Oxford district are both normal and ideal One comes across women who have an almost painless first stage of labour and only some acute discomfort and a few expulsive pains in the second and third stages If there were the usual cases the question of applying anæsthetics in normal labour would not arise The present investigation was undertaken to try to find out what there was in environment physique, or general conditions which gave one normal woman an easy labour while others apparently as normal suffered so acutely

With this object in view an exhaustive analysis was made of the notes of cases taken in during the last two years at the Oxford Maternity Hospital Each detail was tabulated and a comparison made between the short and long labours From this it was found that one factor stood out prominently as being associated not with short but with long labours This was the presence of a septic focus in the mother as indicated either by a note made by the antenatal doctor or by a rise of temperature during the puerperium

After the notes had indicated this point the hospital cases for the five years 1926 to 1930 inclusive were tabulated as to age parity pelvic measurements and weight of baby (to cut out all cases of disproportion) presentation the time of the first stage and the total length of labour respectively and the presence or absence of any evidence of a septic focus in the mother All cases of disproportion, malpresentation, placenta praevia and abnormality other than sepsis were excluded and only L O A cases considered (For the last two years R O A cases are given for comparison) These normal cases were divided into four groups—country primiparas and multiparas and town primiparas and multiparas—in order to see if the country women suffered less than their town sisters as is the general impression of those working among them

The B M A standard was at first taken as indicating a + temperature but it was soon found that this did not cover the cases in which notes had been made of a septic focus during the antenatal period Many of these cases showed a rise to only 99° F on three or more occasions during the puerperium and this latter standard was therefore taken as indicating the presence of some chronic septic process, even when no note had been made of such by the antenatal doctor This is again of course, a purely arbitrary standard, and probably all cases with a rise of temperature to 99° should be suspect However for the purposes of this investigation a rise of temperature to 99° on three or more occasions during the puerperium (usually ten days) is that called a + T° although it is likely that a number of cases in which there was a more or less dormant infection are included in the negative cases

The most common chronic infections noted were

Septic teeth	17 7 per cent
Tonsillitis	2 9
Chronic rheumatism	2 5

while a previous septicæmia or mastitis and gonorrhœa all amount to about 1 per cent of the total cases

Since the average figures for each group do not indicate the frequency with which short labours occur some of the actual figures are given

TABLE I—*Total Percentage of + T° Cases Among Town and Country Cases (all Types)*

13 − T	5 3 "	6 "	29	7 5 "

Note—The average time for the primiparas in the above table was 14 hours.

The above tables show that in the year 1926 the number of patients coming from the country districts who had a

even any induction of this measure, in fact the condition of the patient after operation is much improved. Case 16 is a possible exception to this but we are satisfied that the pre-operative condition was amply sufficient to account for the fatal result.

Illustrative Cases

Out of a series of cases of acute obstruction treated at St. Thomas's Hospital since May, 1931, the following have been elected to illustrate the value of spinal anaesthesia from several points of view. In all cases the drug employed was procaine (hydrochloride of a butyl oxy cinchonine and diethylethylene diamide).

Spontaneous Reduction of Hernia

Case 1.—Male, aged 67. Right inguinal hernia for twenty years. Sudden onset of abdominal pain and vomiting on day of admission. Hernia was irreducible. Treatment: Spinal. Hernia partially reduced. After condition satisfactory.

Case 2.—Male, aged 55. Umbilical hernia for ten years. Irreducible for seven days. Complete constipation and faeculent vomiting for two days. Patient very ill, abdomen distended. Treatment: Spinal. Spontaneous reduction with copious evacuation of bowel. Operation postponed. Recovery excellent. Radical cure of hernia ten days later.

Case 3.—Male, aged 40. *Umbilical hernia for six months.* Strangulated for twenty hours. Colicky abdominal pain. Hernia irreducible. No vomiting, or abdominal distension. Treatment: Spinal. Spontaneous reduction followed.

Stricture as Cause of Obstruction

Case 4.—Male, aged 70. *Abdominal pain for three weeks.* Vomiting and complete constipation for one week. *Old abdominal scar.* Abdomen distended and tender. Auricular fibrillation of some hours' standing. *Very poor operation risk.* Diagnosis: Acute obstruction probably from a band. Treatment: Spinal. Bowels were evacuated and operation deferred. Discharged from hospital. Bowels open regularly.

Case 5.—Male, aged 81. Alternating diarrhoea and constipation for nine months. *Colic and constipation for forty-eight hours.* No vomiting. Abdomen grossly distended. Inoperable *carcinoma of rectum.* Considered unsuitable for operation. Treatment: Spinal, which was *followed* by evacuation of the bowel in fifteen minutes. Condition after anaesthetic satisfactory. *No further obstructive signs but* died six days later. *No post mortem examination.*

Case 6.—Female, aged 72. *Operation had been performed for carcinoma* of sigmoid. Secondary growths present. Lateral anastomosis was performed. After four days signs of obstruction developed and there was faeculent vomiting and abdominal distension. Treatment: Enemata, purgatives and enemata failed. Spinal was *given—immediate evacuation of the bowel* and uninterrupted recovery.

Note.—Spinal anaesthesia was used as a therapeutic measure in Cases 5 and 6.

Early Evacuation Following Relief of Obstruction

Case 7.—Female, aged 65. Incisional hernia for fifteen years, strangulated for 2 days. Abdomen distended. Vomiting present. Treatment: Spinal. Obstruction was in the small bowel. Reduction of gut followed immediately by evacuation of *bowels. Very well next day.* Recovery uninterrupted.

Case 8.—Male, aged 64. Five months right femoral hernia strangulated for several hours. Suffering from haemochromatosis, diabetes and pulmonary tuberculosis. Treatment: Spinal. Sac contained plum-coloured but viable small bowel. Reduction and immediate evacuation of bowel followed. *Good recovery.*

Case 9.—Male, aged 74. Right inguinal hernia for one year. Colicky abdominal pain, constipation and vomiting *for five days.* Chronic bronchitis and glycosuria present. Strangulated hernia and abdominal distension. Treatment: Spinal. Bowel was plum-coloured and viable. Reduction followed immediately by copious evacuation. *Good recovery.*

Evacuation Through Stoma

Case 10.—Male, aged 50. Had ten *previous operations* for perforated gastric ulcer, liver abscess and obstruction. Colicky abdominal pain, vomiting and constipation for five days. No result from enemata. Abdominal distension and faeculent *vomiting present.* Treatment: Spinal. Ileostomy performed, which immediately drained copiously in gushes synchronous with the peristaltic waves. *Good recovery.*

Case 11.—Male, aged 16. Operation for removal of gangrenous appendix was followed twelve days later by vomiting and colicky pain. During the next six days obstructive symptoms gradually increased. Abdominal distension and *frequent vomiting present.* Treatment: Spinal. Ileostomy performed. Bowel immediately emptied very well. Discharged fit nineteen days later.

Case 12.—Male, aged 60. Colicky abdominal pain for five days. Vomiting and absolute constipation *present.* Abdominal *distension. Tumour felt* high up per rectum. Enemata given with no result. Treatment: Spinal. Carcinoma of sigmoid found. Paul's *operation performed.* Bowel evacuated well on table. *Recovery uneventful.* Readmitted one month later for closure of colostomy.

Case 13.—Female, aged 68. Seven days abdominal colic with *absolute constipation.* Very distended. Fixed carcinoma of rectum felt per rectum. Treatment: Spinal. Colostomy performed. Opened at once and drained very well immediately. Very *good recovery.*

Cases Requiring Anastomosis

Case 14.—Male, aged 47. Attacks of abdominal colic and vomiting for three months getting worse. Abdomen distended. Vomiting present. Treatment: Spinal. There were strictures of small gut due to secondary growths. Peristalsis vigorous. Two lateral anastomoses performed. Difficulty experienced in performing anastomosis since proximal loops had not been first drained and the vigorous peristalsis caused distension of the suture line. Died five days later. *Post mortem* examination: Obstruction not relieved. Diffuse carcinomatosis of intestines with fibrosis. Anastomoses sound and had not leaked.

Case 15.—Female, aged 48. Operation for pyosalpinx 1929. Admitted *with* five days' absolute constipation, vomiting and severe abdominal pain. *Abdomen distended and tender. rectum ballooned. Faeculent vomiting present. Very ill. Treatment:* Spinal. Small gut gangrenous and obstructed by a band. *Resection of 18 inches of small bowel. Contents of* proximal loop drained and end to end anastomosis performed easily. Very fit for three days. Died. Post mortem examination: General peritonitis. Suture line quite sound but another loop found to be gangrenous.

Case with Severe Collapse

Case 16.—Female, aged 66. Acute small bowel obstruction *for four days.* Obese, collapsed and cyanosed. Very distended. Faeculent vomiting present. Treatment: Spinal. Gall-stone obstruction in the lower ileum. Removal of stone. Died six hours later. This patient was almost moribund and the advisability of operation was doubtful. The operation was long and difficult and in the opinion of the anaesthetist her condition was no worse at the end than at the commencement *of the operation.* We are satisfied that the anaesthetic was in no way responsible for the fatal termination.

We quote this case to show that spinal anaesthesia can be given to a patient *in extremis* without in itself producing a fatal result.

We are indebted to the surgical staff of St. Thomas's Hospital for permission to publish their cases.

OBSERVATIONS ON THE TREATMENT OF CHRONIC ULCERS OF THE LEG

BY

M UMANSKI M D BER L S A LOND

LATE MEDICAL SUPERINTENDENT HELPER TO ST JAMES HOSPITAL LEEDS

In recent years considerable attention has been directed to the treatment of chronic ulcers of the leg and a number of important contributions have been made to the discussion of the problem The British Medical Association instituted a collective investigation of the subject amongst members of the profession and issued in 1928 a very valuable report by A P Luff embodying the results The importance of the question was also urged last year by A Dickson Wright in an address given before the Medical Society of London in which he estimated the incidence of chronic ulcer of the leg in this country as 1 in 180 and stressed the grave economic loss resulting *from disablement caused by this very chronic and intractable condition* Another important aspect of the leg ulcer problem is in my opinion the sanitary one because every indolent ulcer of the leg is the breeding ground of a great variety of pathogenic organisms—staphylococci streptococci and others Sabouraud defines these ulcers as chancre streptococcique There is a certain potential danger of infection from such patients to those around them especially if erysipelas happens to complicate the ulcer and the patient becomes afterwards a carrier of this disease The crowded conditions under which the poor live makes the spreading of any infection so much easier In a woman of child bearing age such an ulcer may become a potential source of sepsis during her pregnancy or puerperium There is also a possibility of conveying sepsis to a maternity case by the handy woman suffering from a neglected leg ulcer if she is in attendance on the case

TREATMENT IN COMMON USE

Of remedies and methods recommended and used for the treatment of chronic ulcer of the leg there is an amazingly great number and it would be difficult to enumerate them all here Amongst the most approved ones in recent times according to Luff's report the following may be mentioned (1) Unna's zinc gelatin impregnated bandages (2) the skin grafting method (3) injection of sclerosing solution into varicose veins (4) ultra violet radiation

The sclerosing injection of veins has, in practice not entirely justified the early hopes and expectations of its advocates According to Professor Sicard who introduced the method in 1916 there are some contraindications to it and it gives good results only in ulcers of moderate size with no considerable secondary changes Moreover in order to avoid septic infection he does not recommend starting the injections until the ulcers have been made aseptic and healing This method has also the drawback of not being quite safe and liable to cause complications such as embolism sloughing of the skin and others It is further the deeper veins of the tissues which are concerned in the venous return of blood from the ulcerated surface and these cannot be injected Again varicose veins are very rarely the sole cause of chronic ulcers of the leg and are for the most part only one of the factors in their production There are many people with varicose veins who have no ulcers and there are many cases of chronic ulcers of the leg in which no varices are present At all events a chronic ulcer which is caused entirely by varices on the leg can be relieved by a well fitting bandage and antiseptic dressing

Experience shows that none of the above methods is by itself sufficient to effect a cure or even to afford relief in all cases of leg ulcer Even a combination of them as in A Dickson Wright's method does not always bring about such a result Moreover as a preliminary to all of them the ulcer must be brought to a healthier and more aseptic state As to the extensive callous ulcer of the leg of many years standing most of the dermatologists are agreed that very little can be done for them and the surgeon recommends amputation of the limb as the best treatment for such cases

The method recommended by A Dickson Wright for which he claims good results deserves mention here In his own description the details of treatment are as follows (1) The uppermost varicose veins are injected with a 5 per cent solution of sodium morrhuate (2) The leg is bandaged very firmly and evenly (3) Absolute abstention from local treatment of the ulcer No cleansing no ointments —no matter how foul how deep or how long standing the ulcer (4) Extensive ulcers are skin grafted (5) Permanent support of the limb by an elastoplast bandage or a Bourgeaurd bandage The disadvantages of the method *in Dickson Wright's own words are (1) Eczema under* the bandage (2) A generalized eczema on face and forearms although rare very annoying (3) Occasionally a generalized dermatitis (4) Itching (5) Recurrence To these may be added discomfort from tight bandaging for a few days to which many patients may object even for a shorter space of time In view of these disadvantages as well as the fact that a certain surgical skill is required for its practice the method will probably fail to commend itself to the general practitioner In old people with arteriosclerosis it would scarcely be endurable and not devoid of risks

THE PRINCIPLE OF RATIONAL TREATMENT

Before describing my method I should like to make a few remarks on the physiological and pathological principles on which it is founded as well as describing the therapeutic nature of the remedies used in it

In devising this method of treatment of chronic ulcer of the leg I considered that whatever the original cause of an ulcer may have been the essential conditions for its persistence in not healing—that is its chronicity—are (1) the presence in the sore of bacteria and their toxins acting destructively on the tissues and impeding healing (2) certain trophic changes and lowered vitality in the tissues with resulting diminished resistance to bacterial action The chief indications for the treatment of a chronic non specific ulcer which form the basis of my method thus resolve themselves into (*a*) combating the microbic infection and preventing reinfection by the use of suitable antiseptic remedies (*b*) improving the nutrition of the tissues and stimulating their natural power of repair by remedies promoting granulation and epithelization To fulfil the first indication I use a 1½ per cent solution of hydrogen peroxide which is equal to the *B P* solution containing 10 volumes of oxygen diluted with an equal volume of water I consider this solution the best antiseptic for the initial disinfection of an ulcer since it acts quickly by means of the liberated oxygen on the bacteria (anaerobic and others) destroying them and mechanically dislodging them as well as the debris of dead cells and leucocytes from the deeper parts of the sore and so assisting in their removal from the ulcer The oxygen liberated from the H_2O_2 solution acts at the same time as a tonic on the devitalized tissue cells it also causes a certain amount of local active hyperaemia by its mild irritation of the tissues with resulting beneficial leucocytosis

The hydrogen peroxide solution not being suitable for prolonged disinfection some other antiseptic must be used for this purpose I have found from long experience and recent bacteriological tests that balsam of Peru is the most suitable one as it combines good antiseptic properties with valuable granulating and epithelizing qualities It is safe in use being non toxic and does not decompose at pro-

tects granulation, and makes easy the removal of the dressing. Balsam of Peru has been known as a healing remedy for centuries and owes its parasiticidal (in cubes) and disinfectant properties to benzyl and other esters of benzoic and cinnamic acid. It has been used *in combination* with silver nitrate in the treatment of ulcers in the form of ointment. Balsam of Peru is insoluble in water and almost all substances except chloroform and alcohol. The emulsion prepared with gum acacia is ineffective. After many experiments I found that glycerin mixes well with the balsam when 5 to 10 per cent. of alcohol (70 per cent.) is added. This makes a uniform and not too viscid solution suitable for dressing wounds. An 8 to 12 *per cent. solution of* the balsam has considerable antiseptic properties and proved very successful as a dressing for ulcers and wounds.

The value of glycerin in my *method* is not only in its being a good solvent for the balsam of Peru but also in its antiseptic and osmotic properties which render it a superior vehicle to vaseline, lanolin, etc. As an antiseptic it inhibits the growth of bacteria by abstracting water from their protoplasm without injuring tissue cells. *Its bacterial* and *leucocyte properties make it hypertonic*; thus causing an active flow of lymph and leucocytes *from the* surrounding tissues which washes out the organisms embedded in them and so drains the ulcer. The lymph contains antibodies according to Sir A. E. Wright's theory, has a certain valuable bactericidal action on micro-organisms. *Over the hypertonic* salt (5 per cent.) solution (used in Sir A. E. Wright's method) glycerin has the advantage that it does not irritate the tissues or cause pain as does the concentrated salt solution and is more suitable for routine ambulatory treatment. Glycerin also possesses antiseptic properties which the salt (5 per cent.) solution does not. I have for many years used glycerin solutions of antiseptics (boric acid, iodine, thymol, etc.) in the treatment of infected wounds in preference to aqueous solutions. But although glycerin has thus a certain antiseptic action it is much below that of the 10 per cent. solution of balsam of Peru in glycerin, as I was able to prove from bacteriological control tests.

The Method in Detail

1. At the first dressing the affected limb is washed with soap and warm water, the ulcer is cleansed with sterile water or physiological salt solution.

2. A *pad of sterile non medicated wool or lint* is soaked in a 3 per cent. solution of hydrogen peroxide (equal to the *B.P.* preparation diluted with an equal volume of water). It is then wrung out and is applied to the ulcer for half to three quarters of an hour. From time to time some of the hydrogen peroxide solution is poured on the wool to keep up the concentration of oxygen in it.

3. After three quarters of an hour the wool is removed and the surface of the ulcer is dried with sterile gauze. A dressing of gauze soaked in an 8 to 10 per cent. solution of balsam of Peru in glycerin to which 5 per cent. of alcohol is added to assist solution is placed on the surface of the sore and covered with a pad of sterile non-medicated wool which is kept in position by a roller or crepe bandage applied from the foot to the knee without much compression. The leg should however be raised while the dressing is being applied.

4. If ulcers [illegible] the first few days twice [illegible] there is no discharge [illegible] wound and subsequently [illegible] with the [illegible]

begun the strength *Evacuation Through Stoma*
be reduced to 5 or aged 50. Had ten previous operations for
to protect the edges ulcer liver abscess and obstruction

Summary

From many years experience in general practice confirmed by recent clinical and bacteriological tests I came to the conclusion that

1. Even the most extensive ulcers of the leg of non-specific character may heal under adequate ambulatory local treatment provided the patient's general health is not too greatly impaired.

2. The treatment should be directed towards eliminating microbic infection and stimulating the inherent natural forces of repair of the damaged tissues.

3. A solution of 8 to 12 per cent. of balsam of Peru in glycerin and alcohol answers this purpose best since not only has it a bactericidal action on the pyogenic organisms of the ulcer but it simultaneously *promotes* repair of damaged tissues by stimulating the granulating as well as the epithelization process.

4. Glycerin acts as a good excipient for the balsam of Peru and is useful as an exosmotic and hypertonic for draining ulcers and intensifying the antiseptic and penetrative action of the balsam of Peru.

5. Other methods should only be used after the above has been given a fair trial.

6. In ulcers of distinctly varicose character some support of the limb by elastic bandages may be applied for some time preferably only during the day time.

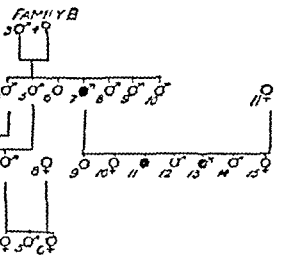
OBSERVATIONS ON THE TRE CHRONIC ULCERS OF a OBSTETRICAL



BY

M UMANSKI, M D BERN

LATE MEDICAL SUPERINTENDENT HEP

D EPILEPSY

In recent years considerable epilepsy is much in dispute to the treatment of chron which has been ascertained number of important cont as a small contribution to the the discussion of the prob ciation instituted a colle amongst members of a very valuable report The importance of year by A Dickson the Medical Societ incidence of chr 1 in 180 and from disablem able condition ulcer prol because eve

ground of attended this man for over years He began to staphyloco have epileptic fits at the age of 8 as he grew older these ulce they increased in frequency—both minor and major certain pr attacks He died in hospital in 1925 of status to those epilepticus at the age of 26 He had consider complica able musical talent and had been proficient with the clarinet and piano

a carr Died at age of 7½ of fits following an attack by under w a savage dog infection Stillborn age sui and 6 Normal during Committed suicide by jumping into canal aged 35 possil he was in no financial or domestic difficulties and hav seemed perfectly normal half an hour before the if sh suicidal act

—1 Now aged 63 and my chief informant There is no history of epilepsy in his family I have known his mother brothers and sisters for over twenty t years

g 2 3 and 4 Normal 2 died of yellow fever in South a America aged 37

ti 5 Epileptic fits began at the age of 26 He was a professional cricketer but owing to these fits he l had to give up His friend equipped him with a small lending library which he still keeps

6 Mother of IV 1 Never had fits died aged 61

7 8 9 10 12 14 and 15 No history of epilepsy

11 Had severe epileptic fits Fell into the fire during a fit and died in hospital of burns

13 Had epileptic fits—frequent spells with periods of quiescence still alive

II —1 Unaffected

2 Unaffected Mother of III 6 and grandmother of IV 1

3 No history of epilepsy but had violent fits of anger and friends avoided him on this account Sudden resentment at an objectionable remark caused him to hang himself at the age of 50

4 Unaffected

5 Dropped dead at his work aged 30

6 8 9 and 10 Unaffected

7 Epileptic fits commenced about the age of 39 or 40 Did not work afterwards and died at the age of 60

I —1 2 3 and 4 Unaffected

This pedigree is small and incomplete especially with regard to the descendants of Generation III It shows however five true epileptics in twenty five descendants of I 3 and I 4—family B in three generations 1 in F_1 3 in F_2 1 in F_3 generations IV 3 stillborn is omitted in this enumeration and IV 2 is not reckoned an epileptic because the evidence for epilepsy is not conclusive This enumeration gives 20 per cent of epileptics in the descendants of I 3 and I 4 and points to a strong hereditary factor In the descendants of I 1 and I 2—family A—there are two impulsive suicides—II 3 and IV 5

As IV 1 was the worst case of epilepsy I have seen the question has occurred to me whether III 6—mother of IV 1—acted as a carrier in her germ cells from both her paternal and maternal sides of a loss of inhibiting factors on cerebral function This loss would seem to be sub lethal in effect for her family became extinct in a few years Does this point to natural eugenic factors tending to preserve the normality of the race? If this operates they do so only in the severer types of the disease the milder forms survive and propagate This seems to be in accordance with the transmission of mental defect and Berry and Gordon in their book *The Mental Defective* classify idiopathic epilepsy as a special type of mental defect

In this pedigree the age of onset varies from 8 to 40 years and this should be borne in mind when studying pedigrees of epileptic families It may be that some die before the age of onset and are classed as normal This is a fallacy which should be remembered when an attempt is made to draw any conclusions as to the relation of heredity to epilepsy

Warrington J S MANSON M D

DEATH FROM RUPTURE OF THE LIVER IN A NEWBORN INFANT

The following case seems to be worthy of record for rupture of the liver as the cause of death of the newly born infant appears to be rare Most of the textbooks on midwifery do not mention it and reports of such cases in the literature are exceedingly few

On March 1st 1932 Mrs A aged 22 a primipara was *delivered of a male infant weighing 10 lb 14 oz* The labour lasted about twenty three hours the presentation being left occipito anterior and terminated naturally but with considerable laceration of the perineum The infant started to breathe shortly after the head was born There was a good deal of delay in the birth of the shoulders and towards the latter part of this delay breathing ceased and some cyanosis became apparent After the birth of the shoulders breathing restarted with slight stimulation Neither shaking nor compression of the chest was used

The child was well formed and apparently quite healthy On the second and third day it seemed quite well and was fed from the breast On the fourth morning it was observed that it was slightly jaundiced but otherwise well In the afternoon the nurse noticed that the child seemed weak and listless and *from that time the weakness increased until* at 6 A M on the fifth day it collapsed and died

At the post mortem examination two hours after death there was slight jaundice and marked pallor of the lips and mucosæ The abdomen was tumid and contained fluid The peritoneum on being opened was found to be full of dark liquid blood and all the organs appeared healthy except the liver On the inferior surface of the right lobe was a haematoma the size of half a billiard ball full of dark blood and about the centre of the haematoma there was an irregular half an inch long incision in the capsule of the liver through which blood was leaking Around the edges of the tear was a small soft clot

It is noteworthy that the child lived four days and appeared quite well although the injury to the liver probably took place at birth the child was very large while the mother's pelvis was average in size The haematoma must have gradually increased in size until the fourth day when the capsule of the liver burst allowing a free escape of blood into the peritoneal cavity

H A PRITCHARD LRCP MRCS

H CECIL BARLOW MB Lond

Lincoln LRCP MRCS

These more highly developed than the former are included within the genus *Homo* but are not considered worthy of the specific attribute *sapiens* with which the six living *races of mankind* are dignified The account which the author gives of the circumstances attending the discovery of the three early Piltdown skulls is very interesting and should serve as one of the difficulties which anthropologists have to encounter in obtaining material The book closes with a chapter on the question of the location of the birthplace of mankind

EARLY LEARNING AND TEACHING

Three recent books may well be noticed together They are *The Children We Teach*[1] by Dr Susan Isaacs *The Gateways of Learning*[2] by Margaret Drummond and *Education of the Backward Child*[3] by David Kennedy Fraser All three authors are teachers and writers of much practical experience and well known for their expository powers Their books therefore are authoritative interesting and full of suggestions capable of immediate application Each is intended primarily for members of the teaching profession but in the education of the very young whether normal or retarded alliance between the doctor and the teacher is essential to success and for their effective cooperation in understanding of one another's outlook and methods is of fundamental importance Hence each of these books has a value and interest for members of the medical profession From this aspect the first-named volume is perhaps of most importance It contains less of psychological details than the other two which on internal parallel lines pursue in greater particularity the methods of what may be called laying the foundations *of instruction in oral expression in reading writing* and drawing in spelling and composition and in arithmetic

The point of view from which Dr Isaacs has written her book *is more nearly akin to that of the medical practitioner* She is recording primarily the children's individuals with varieties of feeling understanding and interest undergoing personal development at different rates and in diverse directions and the consideration of the methods of teaching and training by which they should *be dealt with* arises only secondarily or indirectly She is concerned with what is now spoken of as the primary school age from 7 to 11 years and she devotes attention not merely to the children's intellectual development during that period but also to their social development and reactions This is novel and valuable She emphasizes the life of the individual as opposed to that of the non-existent average child and draws a noteworthy distinction between the function of the psychologist who looks at the development of children all round and as a whole whose wider view enables him to see rather more of the broader laws of their development and who has more leisure to find out what children are really like in themselves and the concern of the teacher who is faced with the practical urgency of training children in this class or that school Especially interesting are the sections on children's thinking children's errors and the beginnings of reason and the case of the child who is backward in reading or in arithmetic is not overlooked

Here we use and Dr Isaacs uses the word backwardness of the normal child It would be well if its use could always be limited in this way One obvious criticism of Mr Kennedy Fraser's book is that in his title there is implied a much wider connotation and that he does not give the same connotation to the word backward throughout his volume Indeed it varies very widely There is a continuous curve of variability in mental power from the idiot to the normal person and the distinctions of the mentally defective from the normal of the various classes of defectives from one another and of the dull and backward class of normals from those above them are quite arbitrary though some of them are legally convenient Mr Kennedy Fraser seems to apply the term backward sometimes to the whole class of subnormals *sometimes to the higher grade* feeble minded only and sometimes to the dull and backward class only It would be better to employ the term *retarded in the educational sense* when the whole class is *meant* Even with reference to those commonly referred to as dull and backward it would be convenient to use the former adjective only of those who *are inherently of lower mental power and to restrict the* term backward to those who are temporarily retarded owing to adventitious circumstances which should be overcome Mr Kennedy Fraser not only recognizes but emphasizes this last distinction and considers the various causes of temporary backwardness such as physical disability irregularity of school attendance bad home conditions and even bad teaching He performs a valuable service too in refusing to consider the maladjusted child as in the same category

> Until the conditions of thinking and acting are at least approximately adjusted to the child's intellectual level no satisfactory conditions for feeling can be arranged When ever we come across a child who is obviously unhappy in his school work we ought first of all to find out the level of his inborn capacity and then set him to work on tasks suited to this level If he still remains unhappy then we should *apply the methods of child guidance to discover* and if possible remedy the unsatisfactory features in his emotional environment

There is some evidence however that Mr Kennedy Fraser is inclined to attach a too rigid or disproportionate value to the exact intelligence quotient

In the preface to *Gateways of Learning* Miss Margaret Drummond says that it *is not a book on methods of* teaching This is too exclusive a negative though it is true that no special technique is advocated The aim is said to be to set out the basic facts in regard to the psychological make-up of the child and the psychological relation between child and teacher and in regard to the sphere of subjects to be taught The aim is excellently accomplished

THE HOBBIES OF A SURGEON IN RETIREMENT

Dr PETER MCBRIDE the famous Edinburgh rural surgeon retired from practice as long ago as 1910 and since then as his pleasantly written book *The Philosophy of Sport* abundantly proves has led an active and enjoyable life With wide interests not only in sport but in literature to which he has contributed several books he has solved the problem of retirement and is obviously well provided with what in these circumstances are usually spoken of as hobbies and have recently been described as occupations without financial return The psychology of sport which is much discussed in the ten chapters dealing with various forms and aspects of sport has rarely been seriously considered Dr McBride indeed points out that the nearest approach is to be found in Thouless's *Social Psychology* from which he makes some abstracts In the chapter on health sport and games he pays some attention to the psychological value of golf and

perhaps rather unexpectedly does not give this form of exercise a high place from the point of view of health It is true that he almost apologizes for saying that even two rounds a day will not keep a man in anything like the best possible condition and when the benefit from one day's golf in the week is under consideration suggests that the effect of the tempting lunch at the clubhouse with an extra drink or two thrown in makes it very doubtful if the health balance is really favourable rowing and riding are much better In another chapter he describes in detail the exercises he has practised himself and found more satisfactory than those of the *Army Manual of Physical Training (1914)* and points out that when recommending exercises to patients the medical man should have had practical experience A graphic picture is drawn of the changes seen at ten yearly intervals of friends who originally slim and active become physically lazy connoisseurs of the larder and cellar and as a result florid protuberant in the lower waistcoat area and old before 50 Easily read this book is full of sound advice concealed by the kindly humour of a wise and experienced senior by no means grave

NOTES ON BOOKS

In his well written book *Biology and Mankind*[1] Mr S A McDOWALL who is the author of several other publications on evolution and is chaplain and senior science master at Winchester summarizes the knowledge which a biological student should have as a foundation and deals with evolution heredity and the biological aspects of social and political conditions The volume covers part of the ground of a biological course which has been given to the older boys at Winchester for more than a dozen years and many of their seniors who are wise in reading what is set out in such an attractive style will wish that they had shared this admirable education Rightly convinced that every man should have a knowledge of the established facts of biology the author has set them out in an extremely interesting manner no doubt the result of long experience and has clearly shown the direct and important bearing they have on the future of the race His view of eugenics is thoroughly broad minded and he throws out a warning of the evil days to come if the present birth restriction of the able bodied and able minded continues and procreation among the degenerate and mentally poor is not restrained

Dr H C A LASSEN'S thesis on *Paratyphoid Infections in Avitaminotic Rats*[2] based on his investigations in the State Serum Institute and University Institution of Hygiene Copenhagen is divided into six parts Its purpose is to record clinical observations on infections in diseases due wholly or partly to vitamin deficiency Subjects dealt with are xerophthalmic dystrophy scurvy and rickets spontaneous infections in experimental animals on a diet deficient in one or more vitamins previous experimental investigations on the significance of the diet to resistance against infections and against intoxications with bacterial toxins previous experimental investigations on the significance of the diet on the production of antibodies and the writer's personal investigations A bibliography of recent literature is appended Lassen's main conclusions are as follows (1) vitamin A deficiency disposes in a marked degree to an increased susceptibility to infection especially paratyphoid (2) vitamin B is hardly of any significance as a factor in creasing resistance (3) vitamin C is perhaps of some significance in this respect but its role is disputable (4) vitamin D is hardly of any significance to the organism as far as infection is determined

Little work has been undertaken into the immunological reactions of reptiles since the original researches of Metchnikoff at the beginning of the century Taking advantage of the rich reptilian fauna in South Africa the authors of a recent booklet[10] have undertaken a series of experiments into the subject of bacterial intoxications as well as venoms and antitoxic immunity in these animals Briefly their conclusions are as follows The susceptibility to tetanus toxin varies with the species lizards on the whole being most susceptible and tortoises least so young crocodiles are intermediate and some of the snakes are more or less susceptible Tortoises and crocodiles are relatively susceptible to diphtheria toxin while snakes are more resistant In general all are very resistant to dysenteric and typhoid intoxications Crocodiles are least resistant to viperine venom while tortoises are very resistant lizards being less so Crocodiles show about the same resistance to colubrine venoms tortoises are more susceptible while lizards are more resistant although not so much so as to viperine venom In all the above cases the antigen persists in the blood for long periods and in general rise in temperature accelerates the development of symptoms

PREPARATIONS AND APPLIANCES

ALTERNATIVE ICE BAG OR HOT BOTTLE

We have received from Messrs F Davidson and Co (143 Great Portland Street London W 1) several samples of a new type of combined hot water bottle or ice bag made by Braun of Melsungen The bags are made of red rubber in a variety of shapes for application to different parts of the body After the ice or water has been put in the flattened rectangular neck in which is inserted a malleable metal plate is rolled up and the bag is watertight All the shapes are well designed particularly those intended for the application of heat or cold to the eye and throat The advantages of a rubber bottle which requires no cork or stopper is easy to fill and does not leak are a considerable recommendation for these appliances

CHEAP GOGGLES FOR ACTINOTHERAPY CLINICS

Dr W BEAUMONT (honorary medical director of the Institute of Ray Therapy Camden Road N W) draws attention to a new type of goggle for protecting the eyes of patients having artificial sunlight treatment The appliance made of non flam special intensified material is similar in appearance to the ordinary green tennis eye shade except that it fits closely round the eyes It is impervious to the ultra violet red and near infra red rays is light adjustable easily cleaned and costs only 9d The manufacturers are Messrs Solport Bros 184-192 Goswell Road London E C 2

CRYSTALLINE DIGITALINE AND OUABAIN

We have received from the Laboratory Nativelle Ltd samples of various preparations of Digitaline Nativelle and Ouabaine Arnaud The former product is of considerable historical interest because the isolation of crystalline digitalin by Nativelle in 1872 was one of the fundamental advances in our knowledge of the digitalis glucosides The preparations are biologically standardized and 1 mg Digitaline Nativelle equals 2½ cat units The makers claim that as regard therapeutic effect 0 1 mg Digitaline Nativelle equals 0 1 gram of the international standard digitalis powder Crystalline ouabain was first isolated by Arnaud from the wood of *Acokanthera ouabaio* and was later found to be identical with the active principle of the seeds of *Strophanthus gratus* Ouabain has better defined physico-chemical properties than any other active principle obtained from the various species of strophanthus and has been recognized by the *United States Pharmacopoeia* as a standard for comparison in biological assays The manufacturers point out that these preparations are pure products with an accurately standardized activity and that their exact therapeutic properties have been established by many years of clinical experience

cause of the allergy may vary He found that some of his cases negative to tuberculin, gave strongly positive skin reactions to an endotoxin produced from a haemolytic streptococcus, which he believes to be the organism of acute rheumatism He defines erythema nodosum as a type of hyper reactive tissue response to different bacterial allergens Under this heading can come both tuberculous and rheumatic cases, and it is possible that an epidemic due to the rheumatic type might occur through a carrier of the haemolytic streptococcus, just as Landau's cases arose from a "carrier" of tubercle bacilli In both cases the importance of the occurrence of examples of erythema nodosum lies in the fact that the source should be carefully looked for, and the tuberculous or rheumatic patient who is the cause of the mischief found before further harm is done

AETIOLOGY OF MYOPIA

Recent work and publications on myopia have cast some doubt on the theories and principles which have been held for a long time, and which, up to the present have been considered serviceably correct That there are a great many such theories is in itself evidence that no one satisfactory explanation of myopia exists There is now a tendency among some observers to regard certain types of myopia as physiological—forming part of a continuous series of refractive conditions of the eye which extend from myopia through emmetropia to hypermetropia They endeavour to substantiate this hypothesis by stating that the incidence of various degrees of refractive error when plotted in graph form give a binomial curve But, in order to obtain this curve they have to disregard all cases of myopia showing crescents or alternatively all cases of more than 6 D Even supposing that these omissions are allowable—and many ophthalmologists would not agree —the disproportionate amount of emmetropia results in a serious departure from this curve and has to be explained by arguments not altogether convincing Again new theories challenge the general view that in most cases myopia is due to axial elongation of the globe, for analysis of fifty three emmetropic eyes has shown that considerable variations exist in the refraction of the cornea and lens and in the axial length the total refractive power being the same in all these cases As a corollary to this it is stated that the eye of a myope of 6 D may have the same axial length as that of a hypermetrope of 4 D It has therefore been suggested that there is no sharp line of demarcation between the three states of refraction If only fifty three cases could be found in support of this view out of an admitted preponderance of emmetropia it might be questioned whether they do not really represent abnormalities rather than the true state of the normal eye Other investigators state that what is known as myopic fundus changes are the result of abiotrophic or developmental changes at the posterior pole of the eye and that the axial length of the globe is in fact secondary to the growth of the retina They deny that the condition of the sclerotic coat or the cornea is the primary cause and believe that hereditary myopia is due to an inherited tendency of the retina to grow to a large size If this is actually the case, certain views upon detachment of the retina now widely held would have to be revised The other theories quoted above do not quite fall into line with what is found in practice, and will have to undergo some modifications before they can be generally accepted Nevertheless, new ideas such as these are certainly useful in shaking ophthalmology out of the rut of conservatism, and by calling for a re examination and reassessment of existing theories, they tend to advance the solution of the problems of myopia a step further As Mr Sorsby[1] has lately pointed out, it is in the school that myopia most often commences, and it is there that inquiry must be made into its nature and causation

T H HUXLEY AND ALDOUS HUXLEY

A lecture by Mr Aldous Huxley would quicken anyone's interest but when it is in memory of his grandfather, Thomas Henry Huxley, the anticipatory pleasure is increased[2] Both men make an especial appeal to the medical profession apart from their non Aesculapian activities T H Huxley was a scholar of Charing Cross Hospital, and for a short time a surgeon in the Royal Navy The description of a case of tuberculous meningitis in *Point Counter Point*, and the future of obstetrics outlined in *Brave New World*, suggest that an undergraduate literary society of the hormonic millennium may discuss "Aldous Huxley as a physician" "By what seems a strange paradox," he says "the older scientists survive mainly as artists" That men of letters may survive as scientists would be a stranger paradox But is it improbable? In a brave new world in which only savages quote Shakespeare, may not Wells Shaw Aldous Huxley and the morbid little band of psycho analytical novelists survive only in so far as they have contributed to science? However that may be, the man of science who is also a man of letters has a double chance of survival and T H Huxley as a literary man is still a living force The lecturer therefore approached him as a purely literary critic He prefaced his analysis of Huxley's style with a short disquisition on literary criticism Critics, he said contented themselves too often with the mere application of epithets It was the pattern in which words were arranged that gave quality and intensity to their meaning and it was the business of the critic to show how our judgements are affected by variations in word patterns Discussing the relations between literature and science, he pointed out that while science is investigation it is no less communication without communication it would be useless "But all communication is literature In one of its aspects then science is a branch of literature" He committed himself still further and stated that all communications whatsoever were literature, qualifying this by saying that potentialities for beauty were unequal 'A good account of deep sea fish can never be as richly, variously and subtly beautiful as a good poem about love" He divides Huxley's writings into three classes the purely descriptive, the philosophical and sociological, the controversial and the emotive To describe an object with precision says Mr Aldous Huxley is extremely difficult and for this kind of writing Huxley had a remarkable talent How difficult it is to say

[1] Sorsby Arnold School Myopia *Brit Journ Ophthal* April 1932 217
[2] Huxley Memorial Lecture 1932 T H Huxley as a Man of Letters By Aldous Huxley London Macmillan and Co Ltd

clearly what a thing is, and how it works writers (and readers) of medical articles well know Quoting passages from Huxley's philosophical writings Mr Aldous Huxley shows that his literary style derived its effect from his mastery of rhythm and from the use of caesura sentences The classical use of caesura sentences he says is to be found in the poetical books of the Bible and was a device constantly employed by Sir Thomas Browne This kind of sentence is fitted for 'the utterance of profound rather melancholy aphorisms Huxley never indulged in literary elegances at the expense of accuracy and truth and seldom made use of metaphor and simile His weakest point was Mr Aldous Huxley says vocabulary In his controversial writings he was courteous but 'used every device for the expression of sarcasm and irony' Those who heard and those who read this memorial lecture have the double pleasure of gaining some insight into the methods of writing of two literary artists

IMPROVEMENTS IN THE TUBERCULOSIS SERVICE

The Joint Tuberculosis Council's report on improvements in the tuberculosis service has been published at a very suitable time as it should help to emphasize certain points in Dr MacNalty's report on tuberculosis which we reviewed in a recent issue (April 9th p 675) Its sound observations on the training in tuberculosis of medical students have already been made the starting point of what should be a very valuable discussion in other quarters But in respect of the tuberculosis service itself this all too brief report makes some weighty observations particularly in Section IV on the principles underlying administrative arrangements for a specialist tuberculosis service The list of signatories is worthy of notice in showing that here we have the opinions of men experienced in every possible branch of tuberculosis work and it is doubtful whether if any report on tuberculosis in this country were called for a better body of men could be chosen to provide it Therefore though Section IV may not be so interesting to the general medical public as the other sections it is in some ways the most important of them all It is true that the success of the service depends upon its personnel and thus that every effort must be made to train and attract the right men to it but that is not all that is necessary The administration in some districts is so inconceivably bad and the facilities for proper work so entirely lacking that it is impossible for any doctor to carry out the duties of tuberculosis officer with any semblance of efficiency On the other hand we have in England many areas where the administration is excellent It should not be an insuperable task for those who are centrally responsible to discover these areas examine them and compile a list of the minimum essentials for efficiency The granting of central funds would then surely give the power of insisting on these minimum essentials in all districts We cannot quite agree with the report where it says only large administrative areas can afford (*a*) well equipped dispensaries with x-ray apparatus, (*b*) institutional accommodation for all types of cases The money is there it is only a question of spending it on essentials instead of dissipating it on useless effort It is to be hoped that in conjunction with Dr MacNalty's this report will bear fruit but this section at least must be criticized as being too restrained and condensed One can easily visualize a member of the public health committee of a local county council reading it through failing to grasp more than a quarter of its message and being in no way disturbed in his somnolent complacency

HUGHLINGS JACKSON MEMORIAL

At the annual general meeting of the Section of Neurology of the Royal Society of Medicine on Thursday next at 8 p m Dr T Watts Eden will present the first Hughlings Jackson medal to Sir Charles Sherrington Almost exactly a year ago we published a letter signed by representative physicians surgeons and scientists asking for support for a fund to commemorate the name of Hughlings Jackson A pamphlet has now been issued to subscribers to let them know what has been done with the money raised and to give them a short history of the lectureship and of the events that led up to its foundation and endowment It is written by the treasurer of the fund Dr Wilfred Harris to whose energy in promoting the scheme and tracing out the records Mr Leslie Paton pays tribute in an addendum John Hughlings Jackson, born in 1835 was one of the first four joint editors of *Brain* of whom Sir James Crichton Browne now aged 92 alone remains to us Crichton Browne was the active spirit in founding the old Neurological Society in 1885 and Jackson was its first president Of the ninety-five original members twelve are still alive In 1897 fourteen years before he died the society founded a lecture in honour of Jackson and with some interruptions it has been delivered triennially ever since The last by Sir Charles Sherrington on 'Quantitative management of contraction for lowest-level co ordination' appeared in our issue of February 7th 1931—a few days after its delivery Hitherto no memento or fee has been provided for the lecturer but the fund now raised will suffice to endow the lectureship with a gold medal and an honorarium every three years What remains over after such provision will go towards the purchase of books and periodicals on neurological subjects for the library of the Royal Society of Medicine each volume being marked by a special book plate with Jackson's profile portrait as designed by Mr Percy Metcalfe for the medal to indicate its origin from the fund

MALARIA IN SOUTH AFRICA

In an appendix to the annual report of the Department of Public Health of the Union of South Africa for the year ending June 1931 [1] Professor N H Swellengrebel of the University of Amsterdam has furnished a valuable and exhaustive memorandum on the endemicity and control of malaria in the Transvaal and Natal He discusses fully the social epidemiological and entomological aspects of malaria in the Union and the control of the disease in the Transvaal the sugar belt of Natal and the railways As a result of his observations he can offer some useful suggestions for the prevention of the disease while his conclusions

[1] The Government Printer Pretoria (2s 6d)

confirm certain well recognized facts and difficulties concerning the transmission and control of malaria over the vast regions of tropical and subtropical Africa. A survey of the various South African species of anophelines showed that the chief carriers of the disease were *A. (Cellia) costalis* and *A. (Myzorhynchus) funestus*, and that fortunately the two mosquitos were extremely selective in their breeding places, thus rendering possible the application of "species sanitation." *A. costalis* breeds in muddy pools, open drains, and small collections of water exposed to the sunlight rather than in large rivers or swamps filled with vegetation, and interference with "vleis" and swamps by drainage and clearing might render such places suitable for its breeding. This happy preference for certain definite breeding places renders anti-larval measures simpler and less expensive. Swellengrebel is doubtful naturally about making sweeping recommendations for anti-larval control over vast areas, because the demographical conditions make this application an extremely difficult undertaking, but he suggests that anti-larval measures be carried out tentatively on a limited scale and continuously guided by research. Further, he warns the authorities that anti-larval measures though indispensable for the eradication of malaria should not be regarded as a *sine qua non* for malaria control over the whole of South Africa. He sees no reason to feel discouraged if future experience proves the impossibility of the general application of such measures. A third mosquito, *A. (Cellia) pharoensis*, which breeds in morasses, has been found infected, but so far there is no evidence that this species plays an important part in the transmission of human malaria. Emphasis is laid on the important fact that research in malaria is an essential part of the system of malaria control in the Union. It is proposed that a control station should be established in the Transvaal so as to achieve close co-ordination of the epidemiological and entomological findings. Intensive research would then be possible over a long period on the same spot in order to determine the changes of conditions throughout the whole year. Conditions in the Natal sugar belt differ in some respects from those existing in the Transvaal. In this area estate sanitation makes anti-larval measures against *A. costalis* a practical proposition of considerable economic importance.

THE MANSON MEDAL

The Manson medal for tropical medical research, given triennially by the Royal Society of Tropical Medicine and Hygiene, has this year been awarded to Dr. Theobald Smith, who in association with Kilborne in 1893 showed that red water fever in cattle was transmitted by ticks and at the same time demonstrated the passage of infection through the ova of one generation of ticks to the next. This discovery proved that a protozoal parasite of mammals could be disseminated by the bite of a blood-sucking arthropod. Probably because Theobald Smith was dealing with a disease of cattle rather than a human disease this landmark in the history of medicine received scant recognition though it preceded the better known work of Bruce on the transmission of sleeping sickness and that of Ross on malaria. Furthermore in 1893 Manson's hypothesis regarding the mosquito transmission of *Filaria bancrofti* constituted only half the truth, since he thought man was infected via mosquito contaminated water either by swallowing the escaped microfilariae or through their penetrating the skin of man. Indeed, it was not until March, 1900, when Low demonstrated filarial embryos in the proboscis of infected mosquitos sent to Manson from the younger Bancroft that the true mechanism of their entry during biting was understood. It is thus no overstatement of the case to say that Theobald Smith was the first to transfer the insect transmission theory of protozoal disease from the realms of hypothesis to those of established fact. In 1904 he reported anaphylactic symptoms in dogs and rabbits, and in a letter to Ehrlich wrote the original description of the classical anaphylactic shock in guinea pigs often known as the Theobald Smith phenomenon. In 1907 he proved that it was possible to immunize guinea pigs actively by the injections of a balanced mixture of diphtheria toxin and antitoxin, and two years later suggested further investigations of the method with a view to its ultimate application to human beings, thus anticipating von Behring and Park's work by several years. The previous recipients of the Manson medal have been Sir David Bruce (1923), Senator Ettore Marchiafava (1926), and Sir Ronald Ross (1929).

ROLL OF BIO-PHYSICAL ASSISTANTS

We publish this week as a Special Supplement the complete list of names on the *Register of Bio-Physical Assistants* revised to March 31st. It was in 1928 that the Representative Body of the British Medical Association first drew attention to the need for registration of lay persons to whom medical practitioners could with confidence send their patients for electrical treatment and actinotherapy. A small committee of experts was formed to draw up a scheme, which, after presentation by the Science Committee, was approved by the Council of the Association. In January, 1929, the Court of the Society of Apothecaries of London decided to adopt and to further this scheme for granting diplomas after examination to bio-physical assistants and for the establishment of a register. Regulations were drawn up, and the first *Register of Bio-Physical Assistants* appeared in book form under the Society's direction. Our purpose in publishing the revised edition of this register is to make it widely known to members of the medical profession in a form convenient for ready reference. The entries in Part I. are arranged in alphabetical order, with postal addresses; in Part II. the names are re-grouped geographically. Since the British Medical Association was primarily responsible for the setting up of the roll we hope that members will preserve this Supplement and send their patients who require treatment by light and electricity to technicians holding the Society's diploma.

Sir Arthur Keith will deliver the Stephen Paget Memorial Lecture at the annual general meeting of the Research Defence Society to be held on Wednesday, June 15th, at 3 p.m. in the lecture hall of the London School of Hygiene and Tropical Medicine, Keppel Street, W.C. The title of the address will be announced later.

The Morison Lectures before the Royal College of Physicians of Edinburgh will be delivered on May 23rd, 24th, and 25th at 5 p.m. by Dr. James Collier, on "The pathology and clinical features of some types of peripheral neuritis."

Collective Investigation

INTO

THE INCIDENCE OF CANCER OF THE BREAST, AND ITS HISTORY AFTER TREATMENT

Report by

ARTHUR P LUFF CBE MD BSc FRCP

CONSULTING PHYSICIAN TO ST MARY'S HOSPITAL HONORARY DIRECTOR OF COLLECTIVE SCIENTIFIC RESEARCHES TO THE BRITISH MEDICAL ASSOCIATION

The British Medical Association in 1928 initiated a collective investigation scheme and started with an inquiry into the treatment of varicose ulceration which was followed in 1929–30 by an inquiry into the after history of gastro enterostomy in connexion with both of those investigations reports have been issued[1] In 1929 it was decided to conduct an inquiry into the incidence of cancer and its history after treatment A memorandum was issued to medical practitioners stating that the inquiry was limited to the following conditions carcinoma of the breast cervix rectum and tongue It was to cover a period of one year from October 1929 to September 1930 and practitioners taking part in the inquiry were requested to keep a record of all cases that came under their notice during that period It was stated that the scope of the inquiry was not limited to new cases but was to include any cases that came under their notice during the period under review The object of the inquiry was to obtain precise information as to the previous history of patients suffering from the above mentioned forms of carcinoma of the actual evolution of the disease itself and especially of the first symptom which had called attention to it of the result of any treatment undertaken and of the duration of the disease when treated and untreated Questions were included relating to family history in the hope that the answers would throw some light on the influence of hereditary predisposition on the causation of cancer Forms dealing with the questions to be answered were issued to those members of the Association who were willing to take part in the inquiry

The returns of cases of cancer of the breast only are dealt with in this report The returns for cancer of the cervix tongue and rectum will be reported on later

In determining the results of treatment the cases that survived have been divided into two groups (*a*) the survivals that had been under observation at the time of reporting for less than four years and (*b*) those that had been under observation at the time of reporting for four or more years As a corollary of the one year period laid down in the memorandum a large number of cases were returned which had been under observation at the time of reporting for less than four years although it is highly probable that many of them if they had been kept under more prolonged observation would have passed into the other group of four or more years Therefore in connexion with this report it must be kept in mind that the number of survivals for four or more years in good health after operation does not represent the number which would have been reached if all the cases had been kept under observation for a longer period nevertheless it will be found that the number of cases though comparatively small is of great value in comparing the survival rates under different conditions

[1] *Brit. Med. Journ.* December 22nd 1928 December 14th and 28th 1929 February 2nd 1930

Reports of 1 651 cases of cancer of the breast have been received The reports are analysed as follows

Married cases (living)	877
Single cases (living)	277
Deaths (married and single)	370
Male cases	13
Reports inadequately filled in	115

The 13 male cases and the 115 cases the reports of which were inadequately filled in have been rejected as useless for the purposes of this inquiry The remaining 1 523 returns have been carefully collated and the results are embodied in the various tables followed by the comments made thereon and the deductions that have been drawn

AGE INCIDENCE

The age was not given in 11 cases

TABLE I—*Incidence of Cases*

Age	No. of Cases	Percentage
19–30 years	10	0·7
30–40 "	93	6·1
40–50 " " "	350	23·0
50–60 " " "	493	32·3
60–70 "	353	23·1
Over 70	187	12·3

This table shows that two thirds of the cases occurred in patients of 50 years and over Of the 10 cases under 30 years of age two occurred at the remarkably early ages of 19 and 21 and as a matter of interest the following details of these cases are given

1 Aged 19 years at time of operation Unmarried Lump in breast first noticed by patient one year before complete operation was performed No palpable enlargement of axillary glands Microscopical examination demonstrated carcinoma Prophylactic treatment with x rays was used fortnightly for ten months after operation Patient was in good health at time of reporting (two years after operation) Grandmother died of cancer

2 Aged 21 years at time of operation Unmarried Lump in breast noticed a short time before complete operation was performed No palpable enlargement of axillary glands Microscopical examination demonstrated carcinoma Secondary deposits occurred in abdomen six to twelve months after operation and in spine later Death fourteen months after operation No family history of cancer

CHILD BEARING IN RELATION TO CANCER OF THE BREAST

Among the total of 1 146 married women 844 were parous 250 were non parous and no information was given in 52 cases The parous have been divided into two groups (*a*) those that had less than four children and (*b*) those that had four or more children and in Table II the percentages in the two groups as furnished by the returns of this inquiry are contrasted with the corresponding percentages in the same group of the married parous women in the entire population as calculated from the figures given in Table 19 p of vol xiii of the 1911 Census Report by the Registrar General

TABLE II

No. of Children	Cases from Present Inquiry		Census Figures	
	Number	Percentage	Number	Percentage
Less than 4	644	76·3	1 [illegible]	[illegible]
4 or more	200	23·7	[illegible]	45·0

Attention has been directed by some writers to the possibility of the association of cancer of the breast with the production of a large number of children but such association is not borne out by the figures given in this inquiry since if such an association existed the

percentage of cancer of the breast cases in women that had four or more children would be higher than the 48 per cent of all married parous women whereas it is considerably lower The figures in Table II tend to show that the greater the number of children the less is the liability to cancer of the breast

Cancer of the Breast in Parous and Non-parous Married Women and in Single Women

In Table III the percentage of cancer of the breast in the parous and non-parous married women, as furnished by the return of this inquiry are compared with the relative percentage of parous and non-parous married women in the entire population as calculated from the 1911 Census (reference 1 above)

TABLE III

Married Women	Cancer of Breast Returns of Present Inquiry	Census Returns of 1911 for the Entire Population
Parous	Per cent 77·0	Per cent 83·0
Non-parous	23·0	17·0

The table shows that there is a relatively higher proportion of cancer of the breast in non-parous women than in parous as compared with the relative proportions of parous and non-parous women in the entire population

In Table IV the percentages of cancer of the breast in married and single women as furnished by the returns of the inquiry are compared with the relative percentages of married and single women in the entire population at 45 years of age and upwards as calculated from Table 33 of the general tables of the census report for 1921

TABLE IV

	Cancer of Breast Returns of Present Inquiry	Census Returns of 1921 for the Entire Population
Married	Per cent 75·0	Per cent 85·0
Single	25·0	15·0

The table shows that there is a relatively higher incidence of cancer of the breast in single women than in married as compared with the relative proportions of married and single women in the entire population Tables III and IV taken together apparently show that *there is a somewhat greater liability to cancer of the breast in both non-parous and single women than in the parous and married women* All the above-mentioned statistics tend to support Lane-Claypon's reference[1] to the possible beneficial physiological effects of marital intercourse on the aetiology of cancer

The statistics in Table V have been worked out from the returns of this inquiry to ascertain whether the fertility or non-fertility of women has any influence on the after-operation results

TABLE V

	Survivals for Four or More Years in Good Health after Operation	Recurrences after Operation
	Per cent	Per cent
Married (parous)	25·3	22·3
Married (non-parous)	28·2	24·3
Single	29·1	20·9
Parous that had less than four children	23·6	21·1
Parous that had four or more children	29·1	24·4

From this table it would appear that the influence of fertility or non-fertility of women on the after-operation results is negligible It may be mentioned in addition that the return of the total number of deaths after operation among the parous is practically the same as that among the married non-parous and single women combined

SUCKLING

Information as to suckling was given in 506 of the married cases that were alive after operation at the time of reporting Of these women 429 suckled their children and 77 did not No very reliable information can be gained from so small a number of cases but it was thought desirable to compare the survival rate for four or more years and the recurrence rate in the two groups, and the results are shown in Table VI

TABLE VI

	Survivals for Four or More Years in Good Health after Operation	Recurrences after Operation
Suckled	Per cent 23·5	Per cent 22·8
Non-suckled	23·6	15·6

From this table it would appear that suckling has some prejudicial effect on the after-operation results although it must be remembered that the statistics are obtained from a comparatively small number of cases

FIRST SYMPTOMS THAT DIRECTED THE PATIENT'S ATTENTION TO THE BREAST CONDITION

Information on this point was given in 931 cases (married and single) as shown in Table VII

TABLE VII

First Symptom Noticed by Patient	No. of Cases
Lump in breast	740
Lump and pain	81
Pain	48
Discharge from nipple	35
Retraction of nipple	23
Hardness of breast	9
Enlargement of axillary glands	2

It will be seen from this table that pain alone as a first symptom was present in only 5·1 per cent of the cases

Interval between First Symptom and Operation

The interval of time that elapsed between the first symptom that directed the patient's attention to the breast condition and the date of operation was given in 715 cases (married and single) who all survived after operation and Table VIII shows in column (*a*) the long periods which many patients allowed to elapse before seeking medical aid although in the great majority of the cases operation followed within a few days of the recognition of the condition by the medical practitioner In columns (*b*) and (*c*) are shown respectively the survival rates for four or more years and the recurrence rates among the various periods

TABLE VIII

Interval of Time between First Symptom and Operation	(*a*) Percentages of Time Intervals	(*b*) Survivals for Four or More Years in Good Health after Operation	(*c*) Recurrences after Operation
		Per cent	Per cent
Under 1 month	37·1	31·3	13·9
1-3 months	23·6	29·0	14·7
3-6 months	15·1	23·5	27·0
6-12 months	11·9	23·5	27·1
Over 1 year	16·2	16·4	34·5

[1] Report No 28 on Cancer of the Breast Ministry of Health 1921 p 103

This table shows the fairly corresponding decrease in the survival rate in good health for four or more years and the fairly corresponding increase in the recurrence rate according to the length of time allowed to elapse between the first recognition by the patient of breast trouble and the operation

Among the returns of deaths after operation information was given in 192 cases of the interval of time that elapsed between the first symptom that directed the patient's attention to the breast condition and the date of operation Table IX shows the respective mortality rates for the different time intervals

TABLE IX

Interval of Time between First Symptom and Operation	Respective Mortality Rate
	Per cent
Under 1 month	5 2
1 3 months	10 7
3 6 months	15 6
6 12 months	25 5
Over 1 year	37 0

This table shows the fairly corresponding increase in the post operative mortality rate according to the length of time allowed to elapse between the first recognition by the patient of breast trouble and the operation

BREAST TROUBLES ANTECEDENT TO CANCER

In only 19 8 per cent of all the cases was any history obtainable of breast trouble preceding the cancer The various forms of such trouble are given in Table X The form of injury in the majority of cases was a blow of some kind but the history of the injury was in many cases of a somewhat dubious nature

TABLE X

Breast Troubles Antecedent to Cancer	No of Cases
No history of any trouble obtained	1,221
Injury	139
Chronic mastitis	73
Abscess	37
Sore nipple	30
Lactation	24

Preceding breast troubles do not appear to be a factor of much importance in the development of cancer of the breast

PAIN IN CONNEXION WITH THE GROWTH

Pain was completely absent prior to operation in two-thirds of the cases and in the great majority of those in whom it occurred the pain was not of a severe character

FAMILY HISTORY

This consisted of statements made by the patients to the medical practitioners of any relatives that had died of cancer but it was impossible for the medical practitioners in most of the cases to verify the statements Only 23 1 per cent of the patients gave a family history of cancer the remaining 76 9 per cent stated that they were not aware of the existence of cancer in any members of their families The 23 1 per cent was made up as follows

15 7 per cent gave a history of 1 relative that had died of cancer
2 8 per cent gave a history of 2 relatives that had died of cancer
1 6 per cent gave a history of 3 or more relatives that had died of cancer

As regards the sex distribution of the alleged cancer among relatives—

63 7 per cent gave a history on the female side only
30 1 per cent gave a history on the male side only
6 2 per cent gave a history on both the male and female sides

So far as the results of this inquiry throw light on family history go it would appear that the influence of hereditary predisposition on the causation of cancer of the breast is not a dominant factor

SITUATION OF TUMOUR

TABLE XI

Situation	Incidence
Left breast	9
Right breast	8
Both breasts	1

The situation was further given in the returns according to the position of the tumour in the centre or in one of the quadrants of the breast The tumours in the central position include the small number of cases in which the entire breast was involved

TABLE XII

Situation in Breast	Incidence
Upper outside quadrant	43 9
Centre	9 9
Lower outside quadrant	14 4
Upper inside quadrant	11 1
Lower inside quadrant	6 6

CHARACTERS OF THE TUMOUR

Information as to induration mobility and ulceration was given in 1 470 cases

TABLE XIII

Character of Tumour	Incidence
Induration	4
Mobile	1
Fixed	94 3
Ulceration	1 5

The majority of the cases of ulceration occurred in the inoperable cases and those in which operation was refused

STAGE OF THE DISEASE

This refers to the absence or presence of secondary spread at the time of examination of the patient and when first seen The classification used is similar to that adopted by Lane Claypon (Report No 81 p 17 to the Ministry of Health 1928)—namely

Class A—Axillary glands not obviously involved

Class B—Axillary glands involved but not to such extent as to further spread of the disease

Class C—The disease extends beyond the axillary glands

The relative percentages in the three classes of all the cases including the inoperable cases and those that refused operation are shown in Table XIV

TABLE XIV

Stage of Disease	Incidence
Class A	[illegible]
Class B	[illegible]
Class C	[illegible]

The 73 per cent in Class C is of course [illegible] weighted by the comparatively large number of inoperable cases that occurred among those operated on and those that refused operation This is clearly shown by the rate

percentages in the 130 inoperable cases in which information was given as to the stage of the disease and which are shown in Table XV

TABLE XV

Stage of Disease	Percentage
Class A	4·6
Class B	36
Class C	60·8

Post-operative Results according to the Stage of the Disease

Information of the stage of the disease was given in 626 cases (married and single) which all survived after operation and were alive at the time of reporting. The relative percentages in the three classes are shown in Table XVI

TABLE XVI

Stage of Disease	Percentage
Class A	43·2
Class B	51·6
Class C	5·2

This table roughly represents the proportion of operations performed on the three classes of cases that were alive at the time of reporting. The survival rates for four or five years and the recurrence rates in the three classes are shown in Table XVII

TABLE XVII

Stage of Disease	Survival for four or more Years in Good Health after Operation	Recurrences after Operation
	Per cent	Per cent
Class A	75	19·5
Class B	16	2·8
Class C	3·3	70·0

This table shows the marked decrease in the survival rate and the marked increase in the recurrence rate in proportion to the extent and spread of the disease prior to operation.

DISCHARGE FROM NIPPLE

The returns showed that discharge was present in 80·8 per cent. of the total cases; discharge was present in 6·6 per cent.; no information was given in 12·96 per cent.

NATURE OF OPERATIONS

The number of operations recorded was 1,203, of which 89·2 per cent. were of the complete kind and 10·8 per cent. of the incomplete kind; in many of the cases the incomplete operation had to be performed owing to the advanced and widespread nature of the disease. Of the operations 67 per cent. were performed in hospitals, 31 per cent. in nursing homes and 2 per cent. in private houses.

Of the 971 cases (married and single) followed by survival at the time of reporting 882 were of the complete type. The survival rate for four years and the recurrence rate in the two types are shown in Table XVIII

TABLE XVIII

	Survival for Four or more Years in Good Health after Operation	Recurrences after Operation
	Per cent	Per cent
Married (parous)	29·1	18·8
Married (non-parous)	33·6	4
Single		
Parous that had less than four children	29·1	
Parous that had four or more children		

From this table it would appear that the influence of fertility or non-fertility of women on the after-operation

[1] Report No. 28 on Cancer of the Breast, Ministry of Health, 1924, p. 103.

MICROSCOPICAL EXAMINATION OF GROWTHS

The results of the microscopical examinations were given in 696 cases. These were classified into the following four groups:

1. *Scirrhus*.—This group includes those described as scirrhus and definitely malignant.
2. *Medullary*.—This group includes those described as pleroidal celled, encephaloid, colloid, adeno-carcinoma and glandular celled.
3. *Carcinoma*.—This group consists of those simply described as carcinoma.
4. *Duct cancer*.—This group includes those described as columnar and papillary in ducts.

Among the 696 cases scirrhus occurred in 37·8 per cent. of the cases, medullary in 33·9 per cent., carcinoma in 22·7 per cent., duct cancer in 5·6 per cent.

Owing to the collection of such a number of cases in which reliable micro-copical examinations had been made it appeared that it might be of interest to contrast in the four groups (*a*) the survival rates for four or more years in good health and the recurrence rates, (*b*) the relative proportions of the four types in those that suckled their children and in those that did not, (*c*) the relative age incidence, (*d*) the relative proportions of the four types according to the stage of the disease (see p. 899), (*e*) the relationship of pain to the four types. The results are given in Tables XIX–XXIII

TABLE XIX

Type of Growth	Survivals for Four or More Years in Good Health after Operation	Recurrences after Operation
	Per cent	Per cent
Scirrhus	31·4	16·2
Medullary	47·9	20·4
Carcinoma	33·6	14·9
Duct cancer	35·1	10·8

This table shows that the survival period for four or more years is lower in the medullary type and that recurrences are much less frequent in the duct type and are more common in the medullary type.

TABLE XX

Type of Growth	Those that Suckled	Those that did not Suckle
	Per cent	Per cent
Scirrhus	35·7	41·9
Medullary	30·8	39·6
Carcinoma	4·4	23·7
Duct-cancer	8·1	2·3

This table shows that the proportion of duct cancer is much higher in those that suckled than in those that did not. If suckling has any influence on the development of cancer of the breast the above figures would tend to show that it is rather more prone to produce the duct type; but as the number of women who did not suckle is small no very reliable deduction on this point can be drawn from the returns of this inquiry.

TABLE XXI

Type of Growth	Under 50 Years of Age	50 Years and Over
	Per cent	Per cent
Scirrhus	38·6	61·4
Medullary	44·5	55·5
Carcinoma	41·7	58·3
Duct cancer	44·4	55·6

This table shows that under 50 years of age scirrhus is the commonest type, but that over 50 years of age it is the least common type of cancer of the breast.

TABLE XXII—*The Four Types in Relation to the Stage of the Disease*

Type of Growth	Class A	Class B	Class C
	Per cent	Per cent	Per cent
Scirrhus	46·7	50·0	3·3
Medullary	4·6	49·1	4·3
Carcinoma	48·9	48·9	2·2
Duct cancer	51·3	48·7	0·0

This table shows that the numbers of cases in the A and B group were approximately the same for the four types. No cases of duct cancer were in the C group.

TABLE XXIII

Type of Growth	Pain Present	Pain Absent
	Per cent	Per cent
Scirrhus	40·0	60·0
Medullary	28·0	72·0
Carcinoma	9·2	63·8
Duct-cancer	33·3	66·7

This table shows that the absence of pain is more marked in cases of the medullary type than in the other types. In the great majority of all the cases the pain was not of a severe character.

Among the returns of deaths after operation the results of the microscopical examination of the growths were given in 151 cases, and Table XXIV shows the relative mortality in the four types.

TABLE XXIV

Type of Growth	Mortality
	Per cent
Scirrhus	3·4
Medullary	4·3
Carcinoma	1·6
Duct-cancer	0·7

This table shows that the death rate is much the highest in cases of the medullary type, and is extremely low in cases of the duct type.

All the figures in this section show that cancer of the medullary type is the severest form of the disease.

HISTORY AFTER OPERATION OF ALL PATIENTS ALIVE AT THE TIME OF REPORTING

Information was given in 910 cases as follows:

Survival after operation in good health at time of returns	Under 4 years	51·9%
	4 years and over	27·4
Recurrences after operation		20·7

It is unfortunate in connexion with this inquiry that of the survivals after operation there are so many cases that had been under observation for less than four years at the time of reporting, since it is highly probable that many of them if they had been kept under more prolonged observation would have passed into the other group of four years and over. As mentioned in the early part of this report it must be carefully kept in mind that though the number of survivals for four years and over does not represent the number which would have been reached if all the cases had been kept under observation for a longer period yet the total number of cases has been of great importance in comparing the survival rates under different factors.

Secondary Deposits (Recurrences) after Operation

Information was given in 204 cases as to the times of occurrence after operation of the secondary deposits and the results are shown in Table XXV.

TABLE XXV

Time of Occurrence of Deaths (or Other Events)	Percentage of Deaths
Under 1 year	46
1 to 3 years	42
3 to 6 years	10
Over 6 years	2

This table shows that practically three-fourths of the deaths occur within three years of the operation.

INOPERABLE CASES

The total number of inoperable cases recorded was 1,[illegible]. The reasons given for the inoperability are shown in Table XXVIII.

TABLE XXVIII

Reasons given for Inoperability	Percentage
Disease too far advanced	68
Advanced age	6
Other causes	6
Invalid	5
Complications	5
Threatened	5
Known to be	6
Not specified	3

TABLE XXV

Time of Occurrence of Secondary Deposits	Percentage
Under 1 year	46
1 to 3 years	42
Over 3 years	12

Sites of Secondary Deposits

Information was given in 486 cases of the sites of the secondary deposits after operation. 247 had a single site and 239 in multiple sites. TABLE XXVI shows the percentages of the relative sites in the 247 single recurrences.

TABLE XXVI

Site	Percentage
Axilla	30
Other bone	9
Supraclavicular gland	11
Skin	16
Within abdomen	9
Within chest	5

The multiple deposits occurred in two or more of the following sites: skin, supraclavicular gland, within chest, within abdomen, other bones, pleura, brain.

DEATHS AFTER OPERATION

No attempt can be made from the returns to calculate the post operative mortality of cancer of the breast, the number of deaths returned merely represent such deaths that came under the notice of the practitioners making the returns during the period from October 1929 to September 1930, and therefore bear no actual relation to the total returns.

It was thought desirable to ascertain the relative mortality rates during the different periods that elapsed between operation and death. Information on this point was given in 275 cases (married and single), and the results are shown in Table XXVII.

TABLE XXVII

Time of Occurrence of Deaths (or Other Events)	Percentage of Deaths
Under 1 year	46
1 to 3 years	42
3 to 6 years	10
Over 6 years	2

This table shows that practically three-fourths of the deaths occur within three years of the operation.

INOPERABLE CASES

The total number of inoperable cases recorded was 1,[illegible]. The reasons given for the inoperability are shown in Table XXVIII.

TABLE XXVIII

Reasons given for Inoperability	Percentage
Disease too far advanced	68
Advanced age	6
Other causes	6
Invalid	5
Complications	5
Threatened	5
Known to be	6
Not specified	3

TREATMENT BY X RAYS AND RADIUM

Reports were sent in of 802 cases that received x ray treatment and of 171 cases that received radium treatment. As the methods of radium treatment, the dosage, the number and the duration of the treatments were not given in several of the cases, classification on those lines was impossible. The particulars have been classified in the following groups:

X Rays Employed after Operation as a Prophylactic Measure

This treatment was used in 245 cases.

TABLE XXXIX.—*X Rays as a Prophylactic.*

Time of Employment of Rays after Operation	No. of Cases	Percentage
Within 1 month	83	34·0
1–3 months	93	38·0
3–6 months	10	4·3
Over 6 months	5	2·1
Not stated	54	22·0

Several of the cases were under observation after the treatment for only a comparatively short time at the date of reporting, but the results for all the cases are given in Table XXX.

TABLE XXX.

Result	No. of Cases.	Percentage.
Survivals in good health at time of reporting—		
Under 1 year	23	9·5
1–4 years	59	24·1
Over 4 years	19	7·9
Extension of growth to other parts	37	15·3
Deaths	69	28·4

X Rays Employed after Operation for Treatment of Secondary Growths

This treatment was used in 67 cases.

TABLE XXXI.—*X Rays for Treatment of Secondaries.*

Time of Commencement of Treatment after Operation	No. of Cases	Percentage
Under 1 year	3	4·7
1–2 years	18	28·9
2–4 years	8	11·9
4–6 years	5	7·5

Some of the cases were under observation after the treatment for only a comparatively short time at the date of reporting, but the results for all the cases are given in Table X

	Cases.	Percentage
		4·5
		4

Simple		
Parous that had less than four children	291	
Parous that had four or more children		

From this table it would appear that the influence of fertility or non-fertility of women on the after operation

[1] Report No. 28 on Cancer of the Breast. Ministry of Health 1921, p. 103.

Radium Employed after Operation as a Prophylactic Measure

This treatment was used in 52 cases. Needles or tubes were used in 80 per cent. of the cases, surface treatment in 13 per cent., and seeds in 7 per cent.

TABLE XXXIII.—*Radium as a Prophylactic.*

Time of Employment of Radium	No. of Cases	Percentage
At time of operation	36	69·2
Within 3 months of operation	13	25·0
Over 3 months after operation	3	5·8

The majority of the cases were under observation after the treatment for only a comparatively short time at the date of reporting, but the results for all the cases are given in Table XXXIV.

TABLE XXXIV.

Results	No. of Cases.	Percentage.
Survivals in good health at time of reporting—		
Under 1 year	21	40·4
1–4 years	14	27·0
Over 4 years	4	7·7
Extension of growth to other parts	6	11·4
Deaths	7	13·5

Radium Employed after Operation for Treatment of Secondary Growths

This treatment was used in 52 cases.

TABLE XXXV.—*Radium for Treatment of Secondaries.*

Time of Commencement of Treatment after Operation	No. of Cases	Percentage
Under 1 year	14	27·0
1–2 years	17	32·6
2–4 years	7	13·4
4–9 years	14	27·0

Several of the cases were under observation after the treatment for only a comparatively short time at the date of reporting, but the results for all the cases are given in Table XXXVI.

TABLE XXXVI.

Results	No. of Cases	Percentage
Apparent cure at time of reporting—		
Under 1 year	10	19·2
1–4 years	8	15·4
Secondary growth kept in check	5	9·6
Extension of growth to other parts	18	34·6
Deaths	11	21·2

So far as any deductions can be drawn from so small a number of cases (104 in all) it would appear that radium is of greater benefit as a prophylactic agent than for the treatment of secondary growths.

As regards the four types of cancer (see p. 900) and their reaction to radium, the worst results as shown by the extension of the disease to other parts were obtained in the medullary type.

Comparison of the Results of Prophylactic Treatment

Table XXXVII. shows the survival and recurrence rates among (*a*) the cases that had no prophylactic treatment after operation, (*b*) the cases that had *x* ray prophylactic treatment after operation, and (*c*) the cases that had radium prophylactic treatment after operation. For the [illegible] of this table all the survivals in good health at

the date of reporting are made up The periods during which they had been under observation varied from a few months to several years but the average periods were practically the same in the three groups

TABLE XXXVII

	No of Cases	Survival in Good Health		Recurrences	
		No of Cases	Per cent	No of Cases	Per cent age
(a) Prophylactic treatment after operation	758	689	90 9	149	21 0
(b) X ray prophylactic treatment after operation	166	139	83	36	21 7
(c) Radium prophylactic treatment after operation	45	39	86 7	6	13 3

This table shows that x ray prophylactic treatment after operation is apparently useless since the survival and recurrence rates are practically the same as in the cases that had no prophylactic treatment On the other hand it shows the beneficial effects of radium prophylactic treatment after operation as represented by the higher survival rate and the lower recurrence rate although it must be borne in mind that the number of radium cases is a small one from which to draw reliable deductions

RADIUM TREATMENT WITHOUT OPERATION

This treatment was used in 69 cases Radium needles were employed in 48 cases radon seeds in 13 cases and surface application in 8 cases No useful deductions can be drawn from so small a number of cases especially as they had been under observation for only comparatively short periods at the time of reporting

BRIEF SUMMARY OF RESULTS

1 The liability to cancer of the breast is not increased by the production of a large number of children The results of this investigation tend to show that the greater the number of children the less is the liability to cancer of the breast

2 A relatively higher proportion of cancer of the breast occurs in non parous married women and in single women than in parous married women

3 Fertility and non fertility of women appear to have no influence on the after operation results as shown by the survival rate and the recurrence rate

4 A painless lump was the first symptom that directed the patient's attention to the breast condition in 79 5 per cent of the cases a painful lump in 8 7 per cent and pain alone in 5 1 per cent

5 The longer the interval of time allowed to elapse between the first recognition of the disease and operation the worse is the result as shown by the survival rate the recurrence rate and the mortality rate

6 Preceding breast troubles (injury mastitis abscess sore nipple and Paget's disease) do not appear to be a factor of much importance in the development of cancer of the breast

7 Pain was completely absent in two thirds of the cases and was not of a severe character in the great majority of the remaining cases

8 From the results of this investigation it would appear that the influence of hereditary predisposition on the causation of cancer of the breast is not a dominant factor Only 5 4 per cent of the patients gave a family history of cancer

9 There is a marked decrease in the survival rate and a marked increase in the recurrence rate after operation in proportion to the extent and prolongation of the interval prior to operation

10 The figures in the report show the great superiority of the complete over the incomplete operations as regards both series of results

11 The [illegible] cancer indicate [illegible] form of the disease is known by experience to have a relatively low [illegible] high death rate

12 Under 50 cases of cancer in the [illegible] type and over 50 years of age the [illegible] type of cancer of the breast

13 Prophylactic treatment [illegible] apparently useless

14 Prophylactic treatment with radium after operation exercises a beneficial effect as regards the [illegible] survival rate and the lower recurrence rate compared with the post operative cases that received no prophylactic treatment or received prophylactic treatment with x ray This deduction as to the value of prophylactic treatment with radium is however open to the objection that the number of cases is small only 45 cases

LONDON PUBLIC HEALTH SERVICES

FIRST YEAR OF UNIFIED HOSPITAL CONTROL

Londoners are sometimes accused of lack of civic pride and it is perhaps true that the metropolitan boroughs are not always able to arouse a great enthusiasm of local feeling amongst those who live there But the county of London a county of more than a hundred square miles existing under the largest local government authority in the world is certainly more inspiring The change from the muddle of the last century when the government of London was mediaeval to-day its County Council deputations and criticisms of this or that part of its administration excite the envy of other capitals To take but one aspect the magnitude of its activities in public health—as disclosed in the recently published second volume of the annual Report of the Council for 1930[illegible]—is simply Under the Local Government Act of the year 1929 which was a specially interesting period in the Council's work because of the large number of hospital and institutional services which passed under its unified control Those who have grown up under independent authorities

TRANSFERRED HOSPITALS

The new Central Public Health Committee of the Council consisting of twenty one members of the Council co-opted began its work at the end of 1929 Under the present it has had only one chairman Dr [illegible] Lambert The hospital institutional and other services of the Metropolitan Asylums Board number [illegible] with accommodation for [illegible] boards of guardians for whom [illegible] 27 000 From the moment it received [illegible] these institutions the committee began [illegible] enlargement and it still has [illegible] extension on hand [illegible] the fact that each hospital [illegible] at least one [illegible] month [illegible] committees to deal with [illegible] subcommittees the [illegible] no of whom were [illegible] been noted This [illegible] successfully [illegible] suggested that [illegible] the boards of guardians [illegible] [illegible] were [illegible] Besides [illegible] legislation [illegible] [illegible] The [illegible]

Memorial to the Late R H Todd

As a tribute to the great work carried out by the late Dr R H Todd during his many years of service as honorary secretary of the New South Wales Branch of the British Medical Association the assembly hall of the British Medical Association House in Macquarie Street Sydney was named the Robert H Todd Assembly Hall. During the year Dr Todd was to have occupied the presidential chair of the New South Wales Branch and would have been called upon to preside at many meetings in this hall. On Sunday, February 21st, 1932 the impressive ceremony of dedicating the chamber to the memory of Dr Todd was performed. The meeting was opened by Dr George Bell president of the New South Wales Branch who briefly outlined Dr Todd's career and referred in eulogistic terms to his work his worth, and his lovable nature. Dr Bell was followed by Mr C H Jagger London Dr Newman Morris representing the Victorian Branch Dr I S Mewers representing the Queensland Branch Dr C H Shearman Sydney, representing the Western Australian Branch Dr I Sydney Morris representing the Tasmanian Branch Dr W N Robertson Queensland ex-chairman of the Federal Committee of the British Medical Association and the first chairman of directors of the Australasian Medical Publishing Company Limited Sir Louis Barnett New Zealand Professor I P Sanders Sydney Sir Henry Newland South Australia chairman of the Federal Committee. The depth of feeling shown by the speakers especially those who had known him well was evidence of the love and esteem which Dr Todd well earned during a lifetime of noble endeavour. At the conclusion of the addresses the ceremony of dedication was performed by Sir Henry Newland at whose behest the members of the large gathering stood for one minute with bowed heads in silence.

Infantile Paralysis in New South Wales

The poliomyelitis epidemic that has passed through the State of New South Wales during the past five months appears now to be on the decline. It has generally been considered in New South Wales that the season for infantile paralysis is the latter part of summer and the early part of autumn—that is February to April. The present epidemic was not subject to this rule for it was raging in December, and reached its maximum intensity in January. In previous epidemics there was always a sharp decline in the numbers of reported cases once the fastigium was reached; in this one the incidence remained constantly very high for a period of some seven weeks. This epidemic is further noteworthy for the fact that it has been responsible for a greater number of cases per month than any previously recorded epidemic in New South Wales.

In 1926 the New South Wales Department of Health first made endeavours to obtain immune serum for the treatment of infantile paralysis. The efforts of the Department did not meet with an enthusiastic response. When in 1929 a sum of £5 was offered for every pint of blood, donors were still difficult to find. It became apparent that a committee of some sort was necessary to organize the collection and preparation and distribution of serum to assist in early diagnosis and to obtain the co-operation of medical practitioners in treatment. From the recognition of this necessity the Infantile Paralysis Committee came into being in 1930. The formation of this committee was made possible through the efforts of Sir Charles Clubbe president of the Royal Alexandra Hospital for Children who made a public appeal for funds resulting in the subscription of a sum of £2 000 and who threw his energy and enthusiasm into the work of organization. The committee is composed of the following: Sir C Clubbe (chairman) Dr E W Turfax Dr R Dick Dr Edgar Stephen and Dr A H Tebbutt (honorary director). Dr Karen Helms occupies the position of medical officer and secretary. The Infantile Paralysis Committee has carried out a great deal of important work during the comparatively short period in which it has functioned. Numerous donors have been obtained; this itself was a task fraught with very considerable difficulties not the least of which was an extensive search of the various hospital records; it speaks well indeed for the zeal of Dr Helms that her quest has met with such a large measure of success. Twenty thousand cubic centimetres of serum have been prepared at the Royal Prince Alfred Hospital by Dr A B Lilley the bacteriologist at that institution and centres have been established in various parts of the State where serum may be obtained by medical practitioners requiring it. This is the first occasion on which immune serum had been employed on a large scale in any epidemic in New South Wales. Previously no more than about eighteen patients had been so treated here.

Up to the time of writing some 350 cases of poliomyelitis have been reported in this epidemic and there have been some 40 deaths. An interesting feature is that whereas the epidemic commenced in the metropolitan area of Sydney and during the early stages by far the greater number of cases occurred in Sydney now the incidence is higher in the towns and country and though the actual numbers have decreased the proportions are reversed.

Sydney Hospital Finances

There seems to be no end to the list of hospitals in financial difficulties. It was disclosed at the Sydney Hospital's annual meeting on February 29th that the debt owing to tradespeople at the end of December 1931 was over £20 000. In the words of Mr J Travers M L C chairman of the board of directors the hospital was only carrying on through the forbearance of the tradespeople. Mr Travers also stressed the point that many people now thought it was no longer necessary to make voluntary donations to the hospital under the belief that it was amply provided for by the revenue from the State lottery. The Minister for Health Mr Ely who presided at the meeting admitted that the revenue from the lottery had fallen far short of the Government's expectations. He said he was struck when perusing the hospital's annual report with a statement that read as follows: To enable the hospital to carry on its services to the community with the same standard of efficiency as hitherto it is necessary that it should have a much larger annual subsidy from the Government. The board of directors is determined to keep the hospital going as long as possible. Sydney Hospital has never closed its doors and it is hoped that the Government will help the board to preserve that record. Mr Ely declared that the hospital would have the Government's co-operation. No doubt the hospital authorities feel that an increase in the Government's subsidy would be of considerably greater value.

Scotland

Professor G M Robertson's Successor

The announcement has now been made of the appointment of Dr David Kennedy Henderson physician superintendent of the Glasgow Royal Mental Hospital to succeed the late Professor George M Robertson in the conjoint appointment of physician superintendent of the Royal Edinburgh Hospital for Mental Disorders and professor of psychiatry in the University of Edinburgh The appointment to the chair is made by a joint committee of the University and of the managers of the Royal Edinburgh Hospital for Mental Disorders who presented the funds for the endowment of the chair Professor Henderson was born at Dumfries and after studying at Edinburgh graduated M B Ch B in 1907 proceeding M D in 1913 He joined the Royal Faculty of Physicians and Surgeons Glasgow in 1919 He became clinical assistant under Sir Thomas Clouston at the Royal Asylum at Morningside and later spent some six years abroad—working as assistant physician in the Manhattan State Hospital New York as resident psychiatrist in the Phipps Clinic Johns Hopkins Hospital Baltimore under Professor Adolf Meyer in Munich under Professor Kraepelin and with the late Sir Frederick Mott at Claybury London During the war he served as a major in the R A M C in France Since 1921 he has been physician superintendent of the Glasgow Royal Mental Hospital Gartnavel and lecturer in psychiatry in the University of Glasgow In 1931 he delivered the Morison Lectures in the Royal College of Physicians of Edinburgh taking as his subject Social psychiatry

Edinburgh Municipal Hospitals

A memorandum by the town clerk of Edinburgh upon proposed arrangements with the University of Edinburgh in regard to municipal hospitals and a report of a committee formed by representatives of the Town Council and of the University on the same subject have recently been circulated The memorandum mentions the provisions of the Local Government (Scotland) Act 1929 under which the Corporation with the approval of the Department of Health for Scotland may provide hospital facilities in its area and states that it is proposed to utilize Pilton (formerly a public health hospital) with Craigleith and Seafield (formerly Poor Law hospitals) in order to increase the accommodation at present available in the voluntary hospitals It states that with certain alterations and minor adjustments these hospitals can be rendered suitable for the purposes of general hospitals including teaching On the question of the remuneration of the staff the committee shows itself to be entirely out of accord with modern opinion and the recent practice of other municipal hospitals It suggests that the system of co operation proposed implies that the remuneration of the medical staff would be arranged in such a way that the rules on this subject applicable to the voluntary hospitals would as far as possible apply to the municipal hospitals so that there would not be any competition between them It may be stated in passing that the staffs of voluntary hospitals in Edinburgh receive as yet no payment for the treatment of patients but that in the Royal Infirmary for the past 200 years the staff have been permitted by the managers to hold clinical classes for which they charge regular fees these fees being paid to a clinical account in the Infirmary which is divided annually among the teachers subject to certain deductions The shares payable in respect of the professors are paid not to them but to the University which employs them at a definite annual salary the shares payable in respect of the other physicians and surgeons go to the individuals direct The annual amount received by a physician or surgeon from these class fees amounts approximately to £300 while the assistants receive an honorarium not exceeding in any case £100 per annum It thus appears that the intention of the Edinburgh Corporation is to pay for treatment as well as for teaching a sum much less than that which is generally regarded as the minimum salary of the physician or surgeon employed to render treatment only at a municipal hospital In the policy drawn up by the Labour Party with regard to hospitals it was recommended that members of the senior staff should receive a salary of £500 per annum in return for giving an eight hour week while juniors should give a six hour week at a salary of £300 per annum further the minimum salary recommended by the British Medical Association for such an appointment whether its holder is or is not entirely responsible for the treatment of the patients is for a daily attendance £500 per annum

Health of Dunfermline

The annual report of Dr C Barclay Reckie medical officer of health for the burgh of Dunfermline states that unemployment and bad trade have not prevented a fairly high standard of health from being attained There has been a lower incidence of infectious disease throughout the year, the total number of cases notified being 758 of which 157 occurred in Rosyth The area of which Dunfermline is the centre is well provided with hospitals and out patient departments For a population of 34 954 in the burgh there are seven hospitals sanatoriums and nursing homes available with a total of 471 beds giving one hospital bed per 74 of the population There are seventeen out patient departments provided by or on behalf of the health authority including child welfare clinics school clinics clinics for tuberculosis venereal disease remedial exercises ultra violet rays dental services malnutrition rheumatism etc of these ten are managed by the Carnegie Dunfermline Trust Special attention is drawn in the report to the results of school medical inspection and of the treatment provided for children at various clinics Reference is also made to the work of the Davaar Maternity Home under the management of the Dunfermline and Fife Councils The year 1930 was a record in the history of this home with 323 admissions but in 1931 the figures had risen to 438 Sixteen ante natal cases were admitted for treatment with successful results and there were forty seven cases of abnormal or complicated confinement with a successful result in every case so far as the mother was concerned Of the 282 normal cases 215 were delivered with and 67 without medical attendance There were twelve cases of puerperal pyrexia and one of puerperal sepsis while four maternal deaths occurred during the year due respectively to post partum eclampsia pyelonephritis puerperal septicaemia and pulmonary embolism giving a case mortality of 0 9 per cent

The Hannah Dairy Research Institute

With a view to providing a national centre for research in dairying in Scotland a committee under the chairmanship of Sir Donald MacAlister was appointed by the Secretary of State for Scotland in 1927 and the necessary institute dairy farm and laboratories were erected at Kirkhill Ayr on ground generously presented by Mr J M Hannah A report of the work of the institute for the two years ending March 31st 1932 reveals the lines on which the scientific and practical aspects of dairy farming have been studied concurrently Early last year the new laboratories were opened and primary consideration was given to the possibility of making more use of home grown foodstuffs so that herd owners might be made less dependent on the expensive high protein concentrates Home grown foods are being analysed in order to

determine the quality, as well as the quantity of their protein contents and the comparative nutritive value of proteins of various compositions is being ascertained by feeding trials. Research work has begun on the physiology and biochemistry of milk secretion and progress has been made in elucidating the transport of milk precursors in the blood. It has been established that milk sugar is derived from the blood glucose and that the milk proteins owe their origin—in part at any rate—to the free amino acids. Previous conceptions about the derivation of the phosphorus content of milk have been reversed and the importance of blood investigation has been established in the work of solving the problems concerned in lactation. The actual chemical transformations which lead to the production of milk in the secretory glands are now being explored. In a survey of Scottish tuberculin tested herds it was found that the average number of reactors did not exceed 3 per cent. each year while in well established herds the proportion was much lower. At least 90 per cent. of these reactors were found to have contracted the tuberculous infection from within the source which can therefore be eliminated in future. A grant from the Medical Research Council has been allotted to promote experiments designed to facilitate the adoption of a more general scheme for the voluntary eradication of bovine tuberculosis. Following the discovery that milk fever was accompanied by a fall in the blood calcium content the intravenous injection of calcium gluconate has been successfully employed as curative treatment. It has been shown that such a fall in the blood calcium is brought about by the injection of certain nitrogenous substances which may explain why milk fever presents symptoms typical of tetany. Work on the aspect of the disease is continuing.

England and Wales

The LCC and the Spahlinger Treatment

Public attention having recently been drawn to the Spahlinger method of treatment for tuberculosis, the medical officer of health to the London County Council (Sir Frederick Menzies) has submitted to the Central Public Health Committee at its request a full and technical report on the subject. In a summary he points out that in the past M. Spahlinger's claim has been that he had an effective remedy for tuberculosis but in spite of every inducement he, for many years declined to disclose the precise composition of his preparations so that no conclusive results could be obtained when the investigations were made by other competent observers. On January 29th last at a meeting in a private house in London M. Spahlinger distributed copies of a document purporting to disclose his formulæ. This document was published verbatim in the *Lancet* and *British Medical Journal* of February 6th and contained the only information yet available. Although in the past M. Spahlinger's claim had been to provide a remedy for patients suffering from tuberculosis and the present formulæ, in the popular mind provided a possible method of treatment it was to be noted that the formulæ were actually for the preparation of vaccines to be used for preventive inoculation and no mention whatever was made of these preparations having been used for curative purposes. Although M. Spahlinger claimed that he had disclosed full details of the method of preparation the fact remained that so much information of fundamental importance was missing that no competent bacteriologists working independently from the formulæ would be in the least likely to obtain the claimed preparations. From the information available it was in the opinion of the medical officer of health no evidence that the vaccine was efficacious nor any evidence which would at present justify the trial of this vaccine under the auspices of the Council on human beings. No information was yet available concerning the serum formerly used for curative purposes.

When the report of the Central Public Health Committee on this subject was due to be brought before the Council it was postponed, it being understood that M. Spahlinger desired the opportunity to make some observations to the committee and these will be considered at the next meeting.

Allegations against a Municipal Hospital

Serious allegations were made in a recent issue of the periodical *John Bull* concerning the circumstances of the admission and treatment of a patient in Highgate Hospital. It was alleged that there was delay in attendance of a hospital doctor, wrong diagnosis of the patient's complaint, an unsuitable diet, acute suffering of the patient from thirst and want of nourishment and failure to notify the patient's wife of his serious condition. The article stated that the circumstances taken together formed a terrible indictment of and caused the gravest disquietude as to the general administration of municipal hospitals. A committee of inquiry was immediately appointed by the London County Council and sat for a whole day taking evidence. The members of the committee included Dr. Florence Barrie Lambert, Mr. H. L. Eason and Dr. Henry Robinson as well as a number of lay members. As the result of a close investigation the committee is satisfied that the facts elicited afford no justification whatever for the reflections made on the organization and administration of municipal hospitals. The report concludes: As to the action taken by the proprietors of the periodical in which the article appeared in giving publicity to statements without adequate and proper inquiry and in basing on them an indictment of municipal hospitals we desire to register our disapproval in the strongest terms and to express our sympathy with the medical superintendent and staff of Highgate Hospital as regards the undeserved reflections cast upon them.

Mr. Chesterton at the Marie Curie Hospital

Mr. G. K. Chesterton was the principal speaker at the annual meeting of the Marie Curie Hospital (Hampstead) held at Mrs. Walter Runciman's house on May 6th and contrived in a happy way to bring into relation two great physicists, one of the sixteenth century and the other of the twentieth—namely, Copernicus and Madame Curie. Mr. Chesterton reminded the meeting that the latter although French by marriage was, like Copernicus, a Pole by birth. Copernicus's discovery furnished a turning point in the history of science and was one great example—the discovery of radium was another—of how a great scientific achievement bestrode the continent of Christendom and knit together nations. But with all respect to Copernicus and to the solar system—against which the speaker would not utter a word of disparagement—it was more important to have cured one poor old woman, to have freed her from all fear and reproach of cancer than to have discovered the whole truth about the astronomical universe. Thus as a benefactor of mankind Madame Curie was to be enthroned above Copernicus her fellow countryman. Mr. Chesterton said that he was present merely to pay a private debt in testifying to the great help given to a dear friend of his at the Marie Curie Hospital. He supposed there was some sort of value in that wholly ignorant testimony but beyond that he had no sort of claim whatever to speak in a medical assembly. Miss Chadburn, M.D., chairman of the board of management who presided over the meeting mentioned that the institution at Hampstead had managed to end its second year free of debt, thanks largely to a wireless

appeal by Sir Oliver Lodge Five minutes broadcasting brought in £1 680 Miss Hurdon M D the director said that since the clinic work began in 1925 nearly 800 cases of uterine cancer had been treated by radium most of them from London and the Greater London area Unfortunately nearly three fourths of the cases came in in a very advanced state but of the comparatively early cases all the early operable cases and 82 per cent of the borderline cases were living and with very few exceptions the patients were free from all signs and symptoms of cancer A number had passed the standard five year period During 1931 the number of in patients was 472 and the out patient attendances numbered 1 294 Sir Cuthbert Wallace congratulated the hospital on its achievements and spoke of the value of such team work as the hospital represented

Coroners Inquests in London

The number of deaths reported to the London coroners in 1931 was 8 155 as against 8 037 in the previous year Of these deaths 2 593 took place in mental hospitals and other institutions The circumstances connected with the deaths reported were investigated by the coroners and inquests were held in 3 603 cases a decrease of 274 as compared with 1930 Inquests numbering 166 were held on infants under 1 year of age During the year the coroners directed post mortem examinations in 2 723 of the inquest cases and in 2 486 of the remaining cases in which no public inquiry was necessary A verdict of murder was returned in 12 cases as compared with 11 in the previous year Three inquests were held in connexion with executions Two verdicts of manslaughter were recorded The total number of suicides was 635 an increase of 41 on the previous year Deaths from want of attention at birth have decreased from 34 to 28 In all 2 050 people met their death by accident as against 2 073 in 1930 Injuries accounted for 41 deaths and there were 58 deaths by drowning A verdict of death from natural causes was returned in 609 cases and there were six verdicts of cause of death unknown Inquests on newly born children decreased from 54 to 51 and a verdict of murder of a newly born child was returned in one case In 23 cases it was decided that the child was stillborn Excessive drinking accounted for 50 deaths a decrease of 16 on last year The total cost to the London County Council of inquiries made by the coroners and of inquests held in 1931 was £36 729

Lord Moynihan and Yorkshiremen

Lord Moynihan of Leeds the new president of the Society of Yorkshiremen in London was entertained by that body at a luncheon on May 4th He painted a sombre picture of what London would have been without the incursion of Yorkshiremen or even if while the rest of Yorkshire had sent its quota to the metropolis the contribution of Leeds had for some reason been withheld He gave a list of ten important academic bodies or professional or business associations headed by the Royal College of Surgeons all of whose presidents a year ago were Leeds men He doubted whether any other city not excluding London had so many people holding national positions at the same time Lord Moynihan went on to say that he knew the Yorkshireman inside and out and proceeded to discuss Yorkshire qualities—courage ability to get things done grim taciturnity refusal to admit second best honesty of mind bedrock integrity and refusal to be turned aside by the shimmer on the face of things when searching for truth at the core The chairman at the luncheon Mr J Addyman Gardner praised the Leeds School of Medicine which he said was now the best equipped in the country and owed much to the influence and broad outlook of Lord Moynihan

Correspondence

L C C PATHOLOGICAL SERVICE

SIR,—Recent correspondence in your columns has emphasized the great difficulties which arise in the provision of laboratory services for hospital patients unless the laboratory is in or very near the wards and the out patient department It is important and often essential that specimens for examination should be taken to the laboratory without delay and for some examinations it is desirable that the specimen should be collected by the pathologist It is important also that the pathologist should have access to the ward and the clinician and the patient access to the laboratory I regret discussions and interchange of opinion between clinician and pathologist are as important for the welfare of the individual patient as for the advancement of the science and practice of medicine It is difficult for a pathologist to maintain interest in the examination of specimens sent by clinicians whom he seldom meets from patients whom he has never seen Ideas for research are not likely to occur unless the laboratory worker has easy access to the wards and opportunities for the discussion of cases with physicians and surgeons The clinician will seldom make good use of the laboratory unless it is accessible to him and unless he has ample opportunity of discussing his cases with the laboratory worker

It can I think be regarded as axiomatic that no hospital is adequately equipped unless it has its own laboratory and its own pathologist as an integral part of its establishment The pathologists of the voluntary hospitals have within their own hospitals all the material which they require for investigation and research and they have the opportunity to do good work in close association with their clinical colleagues They would gain no advantage from the examination of a large number of specimens delivered by messengers from the hospitals of the L C C It is true that some of these L C C hospitals are institutions for the care of the incurable but many perhaps the majority are general hospitals which take for medical or surgical treatment cases of acute and chronic disease the same types of acute and chronic disease as the voluntary hospitals Some of these L C C hospitals are new and modern buildings with wards and operating theatres which compare not unfavourably with the best of the voluntary hospitals

The resources of laboratory medicine ought to be as freely available in the diagnosis and treatment of cases within the municipal hospitals as in the voluntary hospitals and each of these hospitals ought to have its own pathologist and its own laboratory It is obvious that the provision of a laboratory for each general hospital with 250 beds under the control of the L C C would involve a large sum of money and it may be necessary to postpone the development of a complete scheme for the municipal hospitals until better times Meanwhile group laboratories have been established and each of these group laboratories does the work of its own hospital and of the hospitals in the adjacent district In the future much will depend on the policy adopted by the L C C and its advisers towards the group laboratories If a policy of centralization is adopted if the group laboratories remain few in number and each is enlarged to deal with an increasing number of specimens sent from outlying hospitals the disadvantages attached to the sending of specimens by post and messenger will prevent the development of an adequate laboratory service but if as I hope and believe it is the policy and intention of the L C C to increase the number of its pathologists

and laboratories the present system of group laboratories can be looked on as a transition stage towards the establishment of a pathological unit in each large hospital As a temporary measure the pathologists of the voluntary hospitals might be willing to help the municipal hospitals but the laboratories of the voluntary hospitals have been provided and equipped for the work of their own hospitals and they could not be asked to cope with much additional work from outside The work of the municipal hospitals could not be done in the laboratories of the voluntary hospitals without additional buildings, equipment and staff Money which is available for hospital laboratories should be spent in the building and equipment of laboratories in hospitals which have no laboratories and not in the enlargement of existing laboratories to enable them to undertake outside work, work for which the clinical laboratories of the voluntary hospitals were never intended

Intercourse and co-operation between the pathologists of the voluntary and municipal hospitals is most desirable and the municipal pathologists will gain much by visits exchanged with their colleagues in the voluntary hospitals The experienced pathologists of the great London medical schools can do much to help their colleagues in the municipal hospitals by friendly visits and advice but it would be a misfortune both for the voluntary hospitals and for the municipal hospitals if the laboratories of the voluntary hospitals undertook routine work from outside and became in effect the group laboratories of the I C C The hospitals of the I C C form a huge group of institutions which contain clinical material unrivalled in amount and variety even by the hospitals of the great London medical schools For this great group of municipal hospitals a liberal provision of pathologists and laboratories is essential not only for the welfare of the patients but for the advance of medical science The municipal hospitals of London contain a wealth of material which can and should provide unrivalled opportunities for investigation and research If these opportunities are to be realized if the patients are to receive the advantages of modern methods of diagnosis and treatment the provision in the I C C hospitals of well staffed and well equipped laboratories is essential —I am etc

FAILURE OF INTRAVENOUS LIVER THERAPY IN PERNICIOUS ANAEMIA

SIR —The case of severe anaemia described in detail by Dr J G McCrie in your issue of April 30th can, without any hesitation be classified as pernicious anaemia The fact that the antianaemic factor was administered by the intravenous route rules out the possibility that the failure to respond to treatment was the result of defective absorption from the gastro-intestinal tract The only satisfactory explanation of the absence of response to treatment must be the impotency of the material employed This is surprising and extremely unfortunate in view of the undoubted beneficial results obtained with the original samples of hepatex P A T by Wilkinson and others Further evidence that the batch of material used by Dr McCrie was impotent is given by my own experience in the treatment of two cases of pernicious anaemia with the same material approximately about the same date A complete absence of response occurred in both cases which subsequently reacted excellently to the administration of liver extract by mouth I understand the manufacturers recognized the impotency of that particular sample and that it has been withdrawn I have since heard that subsequent preparations have been shown by clinical trial to be active

In your issue of February 13th 1932 I described the beneficial effects which followed the intramuscular injection of Ganssen's liver extract issued by Bayer Products Ltd under the trade name of 'campolon In the present issue of the Edinburgh Medical Journal (May, 1932) confirmatory results are published by Dr R M Murray Lyon Since the publication of my paper I have treated two cases of pernicious anaemia with a batch of campolon of extremely poor activity and there is every reason to believe that one of the patients would have died had not blood transfusion been given Eventually both patients responded well to a home made liver extract of my own Bayer Products Ltd inform me that they have received clinical evidence from Germany of a similar kind in regard to this particular sample, which has been withdrawn from circulation A recent sample of campolon which I tested within the past month on two cases of pernicious anaemia was found to be potent

It has long been recognized that impotent brands of liver extract and gastric tissue for oral administration have appeared on the market but it was hoped that the purified and concentrated materials for intravenous and intramuscular injection which have recently been produced would have a constant activity Unfortunately this has not turned out to be so as is clearly shown by the cases referred to above

It would be unfair to blame the manufacturers for this state of affairs, since no satisfactory potency test exists other than clinical trial on patients suffering from pernicious anaemia Impotent preparations will continue to be sold until a suitable method of assay is forthcoming —I am etc,

University of Aberdeen May 5th STANLEY DAVIDSON

ORIGIN OF TUMOURS

SIR —Mr Lockhart Mummery's article The origin of tumours in your issue of April 30th is rather too provocative The aberrant growth theory of cancer dies hard it has shifted from cell surroundings through cytoplasm nucleus and chromosomes and now is settled down in the Hindenburg line of gene mutation—a strong line for the gene is invisible and can be neither proved nor disproved The holders of the infective origin are faced by a hypothesis which admits of neither proof nor disproof

He says "Tumour cells grow by their own division and not by converting neighbouring cells into tumour cells' This is now almost regarded as an adage but does it mean anything? If a section of primary non-allergic tuberculosis of the lung is examined sheets of epithelioid cells, often in active mitosis will be seen—that is arising from their own division In such a case similar metastases of the same type of cell may be found in kidney or spleen This appearance was and probably still is regarded as neoplastic by the ill informed In certain old standing gonorrhoeal warts there are large areas of epithelial cells often showing metaplasia frequent mitoses, and deep penetration into the hypodermis A fragment of such a wart removed from the surface epithelium, would probably be labelled epithelioma by most pathologists Again, the cells have grown by their own division and not by converting neighbouring cells into 'neoplastic cells

But let us grant the theory of gene mutation Then cancer is simply a normal abnormality—that is an error of normal growth It is only pathological inasmuch as unlike Peter Pan it insists on keeping on growing up It is a normal growth and therefore can produce no reaction except by pressure or replacement Do we find this?

We see many signs of intoxication even in relatively early and [illegible] infected cancers, pyrexia is frequent, altera-

tions in the colloidal stability of the blood leading to a multiplicity of tests giving 70 to 80 per cent of positives we sometimes see the spontaneous cure of chronic rheumatism as the cancer arises we frequently find leucocytosis and less often eosinophilia There remains the cachexia which may occur in small and uninfected growths How does a gene mutation cause such symptoms?

Worse still the gene mutation theory absolutely vetoes any hope of medical treatment ever being effective It will be quite impossible to check cancer—that is unrestrained normal growth—without also stopping the necessary growth regeneration of the remaining cells of the body a cure would be followed by death from senility within a few weeks But we find that this does not follow I have described a medical system of treatment practised in a public hospital clinic and have demonstrated cases in which complete regression of malignant growths has taken place—and the patients are alive and well for periods up to four years These cases have been followed by many well known surgeons How can the holders of the gene concept explain this occurrence?—I am etc

Bristol May 3rd A T TODD

SIR —I fear that Mr Lockhart Mummery has like others confused the chemical and morphological ideas of protoplasm Chromosomes and genes are not the efficient causes of the life process but products of it As Ernst Haeckel says they are the phylogenetic outcomes of the manifold differentiations which the originally homogeneous and structureless plasm has undergone in the course of millions of years In short they are the result of evolution which one should note is always orderly and definite

After the death of the cell these differentiated structures remain just as in a cell aggregate like the human body which evolution has made so perfect the differentiated cells comprising the various organs are still present after life has departed and until decomposition sets in But life and growth are not evolution Though evolution cannot take place without life life could occur without evolution Life is primary and is accompanied by chemical changes every minute of the day evolution is secondary and the changes it brings about take generations The two are entirely different things

It is the constant succession of chemical changes in the protoplasm of cells whether structureless or differentiated which constitute life and growth and it is to some subtle alteration in the chemistry of the life process that we must look for irregular manifestations of growth—I am etc

Upholland Wigan May 3rd J THOMSON SHIRLAW

FOULING OF FOOTWAYS BY DOGS

SIR —Many must have rejoiced to see the letter in your issue of May 7th It is urgent that public opinion on this matter should be aroused for the streets of the medical neighbourhood resemble a vast latrine for dogs Both sides of practically every doorstep are soaked with urine Those whose duty it is to clean the doorstep and railings have several times a week to remove excrement frequent doses of lysol and sulphur placed on the stones are not enough to prevent this nuisance Often have I wished that the Japanese custom prevailed here—removal on entering a house of all outdoor footwear For the soiled pavement is cleaned only by rain and the shoes of passers by We may be thankful we do not realize what is left on our carpets If bacteriologists examined the dust in carpet and floor sweepers light might be thrown on the causes of many obscure maladies

Enlightened public opinion can cure all this revolting condition in front of our houses Some thirty years ago not only the pavements but also the floors of all public vehicles were liberally covered with spittoons Within a few years by means of lectures letters in newspapers and notices describing the danger of tuberculosis the aspect of the streets and floors was entirely altered

It is the duty of members of the medical profession to speak to everyone who is attending a dog on a footway or a doorstep to tell them of the dangers of this habit and of the advisability of training the animal to use the gutter—I am etc

London W 1 May 9th AGNES SAVILL M D

CYSTIC DILATATION OF THE COMMON BILE DUCT

SIR —I am led by Mr Julian Taylor's letter on this subject in your issue of April 23rd to report an observation of my own

In November 1926 I operated on a married woman of 30 (three months pregnant) who had had a variable and painful swelling in the right side for five years She was not jaundiced and since pyelography showed a normal pelvis in the right kidney the nature of this cystic swelling was obscure Exploration revealed a cystic dilatation of the common duct Within the cyst two openings were seen on its posterior wall from one of which bile was flowing An attempt was made to reconstruct the duct in the manner of an endoaneurysmorrhaphy while the anterior part of the cyst was sutured to the parietes and drained Six weeks later (as the discharge of bile continued) I reopened the abdomen and identified the openings in the cyst wall as the mouths of the cystic and hepatic ducts No passage towards the duodenum could be found I made an anastomosis between the dilated common duct and the duodenum The patient was discharged on the fifteenth day feeling better than she had done for months and five months later was delivered of her baby

She was readmitted two years later with jaundice fever and a tender swelling of the right hypochondrium A thick walled abscess cavity four inches across in the right lobe of the liver was drained After this she was well for three months then began to have attacks of pain shivering and jaundice I explored the abdomen in October 1930 There was a narrow stoma barely admitting a probe between the duodenum and the distended common duct which was filled with turbid bile The anastomosis was reconstructed with a flap of duodenum and the common duct temporarily drained

A month later she began to be jaundiced again and was readmitted in April 1931 with severe pains in the upper abdomen intense jaundice vomiting and fever She rapidly became worse and died a few days later At the post-mortem examination the liver was found to be riddled with abscesses but unfortunately the relation of these to the bile ducts was not determined

I formed the opinion that the abscess which developed two years after the first operation was due to infection of a pre-existing (congenital) dilatation of an intrahepatic bile duct and this view is supported by the post-mortem finding in Mr Julian Taylor's case If cystic dilatation of the common duct is usually associated with dilatation of the intrahepatic ducts the results of subsequent infection following choledocho-duodenostomy are likely to be serious —I am etc

Hull April 30th HAROLD LEVY

SPRUE IN MALTA

SIR —In the *Journal* of March 12th (p 471) Dr [illegible] reported a case of sprue in Malta and remarked that the chief interest in the case lay in the fact that this being the first authenticated instance of sprue reported in Malta From the history given of the patient having been for years in the Near East —Palestine or Egypt presumably—surely there is no important point in the fact that the case was reported from Malta for it is not very probable

that the disease was *acquired in the Near East* in spite of the length of the intervening period of about thirteen years? It would be interesting to learn details of the patient's condition between the time of his leaving the Near East and the diagnosis of sprue in Malta. The history of cases like this is important, in that they suggest that sprue is the result of a definite infection acquired in endemic regions.—I am, etc.

Sutton Mallet, Somerset, April 30th — H. H. KING, Lieut.-Colonel I.M.S. (Retired), Director, Imperial Bureau of Entomology.

MALIGNANT DISEASE OF PHARYNX AND LARYNX

SIR,—I beg, to say how indebted I feel to Mr. Marcks (April 16th, p. 818) for his lucid and apt classification of throat cancer more particularly from the point of view of treatment. It should however, be clearly remembered in the connexion that if a graft is likely to follow it largely depends upon when rather than how, the treatment—whatever its nature—is employed. If those cases mentioned by Dr. McKenna (May 7th, p. 859) had been subjected to diathermy in the early stages the results might have been different. As regards how diathermy is accomplished I am strongly in favour of diathermy puncture to the malignant area in the throat and of repeated applications over a wider and wider surface; this certainly acts well and when performed on inoperable glands in the neck is most useful in giving relief. The method is simple—namely a long incision over the glandular mass, the skin being freely reflected and fifty or sixty diathermy punctures made into the exposed parts. This is carried out under strictly aseptic precautions, the incision being rapidly stitched up and healing taking place by first intention. This may be repeated at intervals of a few days or weeks.—I am, etc.,

London, W., May 7th — WM. STUART LOW.

THE USE OF THE SELF

SIR,—The review in your issue of April 30th of Mr. F. Matthias Alexander's latest book, *The Use of the Self*, is as full and valuable as could be expected in the space allotted to it, but the contents of the book, and especially of the chapter on "Diagnosis and medical training," merit much more attention than can be given in any review, and should be very carefully studied by everyone who is interested in the advancement of the medical profession. Those who do study this book will, I think, agree with me that if one half of the statements contained in it are true then not only our methods of diagnosis and training but even our conception of disease itself require radical alteration. And Mr. Alexander having arrived at his conclusions by experiment and by experiment only, is prepared to demonstrate the truth of all his statements. May I suggest that it is time the profession as a whole inquired carefully into a theory and practice that will, I am convinced, very shortly prove revolutionary to all our present standards?—I am, etc.,

Manchester, May 9th — R. G. McGOWAN.

SACRO-ILIAC DISPLACEMENTS

SIR,—I have read with great interest your report (April 16th, p. 710) of the discussion on backache and the orthopædic surgeon by the Devon and Exeter Medico-Chirurgical Society. Concerning the question of sacro-iliac displacements however I am not quite in agreement with everything that was said at that meeting, and as during the last twenty years I have seen about 2,000 cases of such displacements I venture to think that a few remarks on the subject may prove of interest.

Sacro-iliac displacements are much commoner than is generally supposed, they may be rotary (the commonest kind) or upwards, downwards, forwards or backwards *en masse*. They pass undiagnosed for the simple reason that they are not looked for. Reposition is quite easy and painless provided that the technique is correct. It must, however, be admitted that this is by no means easy to acquire. I have never used a general anæsthetic in order to produce the necessary muscle and joint relaxation before performing reposition. I find that carefully administered vibrations and gentle passive movements are all that is required to effect this.

Mr. Norman Capener, in the discussion referred to, stated that the osteopath employed manipulations for reposition of vertebræ which have been established as long as medicine has existed. I have never (except during recent years) seen any such manipulations described in medical literature, and I should be glad to know where they have been published.—I am, etc.,

London, W.1, May 6th — EDGAR CYRIAX.

RICKETS AND VITAMIN D

SIR,—I was much interested in the case referred to by Dr. Chalmers Watson in the *Journal* of April 23rd. Some years ago a case of severe rickets in a boy of 9 years came under my notice. He was very stunted, his arms were bowed and the lower limb bones more particularly the leg bones were much deformed; the clavicles were misshapen. There was no albuminuria. He could only walk in a feeble fashion. The condition was very gross; radiographically the bone ends were rickety. He had lost his incisor teeth and further extractions were required. A twin sister was well grown and showed no signs of rickets. The children had been brought up under the same conditions (neither had been breast-fed); the home conditions as ordinarily understood were good and the mother was of an intelligent and careful type. There was a family of eight, two or three of the other members had shown rickety deformity of the lower limbs but had "outgrown" it. The response to the administration of cod-liver oil and various antirachitic vitamin D remedies was slow; the boy being treated in an institution alongside children who made satisfactory progress. He became fairly vigorous but relative dwarfing and a considerable degree of bone deformity persisted. For the latter, osteotomy was performed in each leg.—I am, etc.,

Cosforth, Newcastle upon Tyne, May 3rd — WILLIAM MACKENZIE.

PREPARATION FOR MARRIAGE

SIR,—Two letters signed by Sir Arthur Newsholme and Dr. Allan, in your issue of April 9th on preparation for marriage and the Personal Problems Bureau to be set up by the British Social Hygiene Council raise two quite distinct questions, without suggesting the answers to either. The first concerns the policy of the British Social Hygiene Council on birth control and the second raises the question of who are the experts in the physiology and psychology of sexual relations competent to give advice in preparation for marriage.

With regard to the first Sir Arthur suggests that the National Council for Combating Venereal Diseases was reformed under the euphemistic title of British Social Hygiene Council with the avowed object of preventing these diseases, [only?] by the promotion of chastity and continence, and, in consequence (presumably?) has hitherto refrained from action which would imply approval of artificial birth control. The society published in 1926 an official pamphlet on *The Foundations of Social Hygiene* to which was appended a signed statement on

continence purporting to certify that sexual intercourse is unnecessary from which it followed that the preaching of abstinence was sufficient prophylaxis against these dread diseases Quite apart from questioning the justification for the implicit optimism of relying on the magic of words to lower the incidence of venereal diseases let alone to lower the abortion rate and the illegitimacy rate which are undoubtedly rising by comparison with a falling birth rate we may perhaps be excused a feeling of bewilderment when we find some of the same names appearing both on the cover of the *Foundations of Social Hygiene* and in the list of vice presidents of the Society for Constructive Birth Control and when we discover the same distinguished men of science working with equal zeal for both these opposed crusades

With regard to the second point Dr Allan is concerned with the undesirability of undermining a patient's confidence in the ability of the family doctor by any suggestion that he is not competent to advise on the problems which in a technical sense are sometimes called sexological But as a matter of fact is he? Even the specialist gynaecologist can frequently lay no claim to being in a technical sense a psychologist nor need he be an expert in the technique of contraception The study of the special problems involved in the variable and complex sexual adjustments that are a part of marriage is based on researches that are anthropological sociological and psychological as well as physiological No doubt under the able direction of Mrs Neville Rolfe the Personal Problems Bureau may claim to be adequately certified as trained sexologists but surely general medical practitioners will hardly make that claim?—I am etc

THE SACRUM

SIR,—In the review of *Cunningham's Anatomy* published in to-day's *Journal* I notice your reviewer draws attention to a statement made in the book that the sacrum was a sacrificial bone in ancient times and wonders on what grounds this statement is made In view of this perhaps the following will be of interest to other readers besides anatomists

In the Jewish literature of somewhere between the sixth and the ninth centuries of the present era there is to be found the following legendary conversation between Emperor Hadrian and Rabbi Joshua ben Chananiah (second century) From which part of the skeleton asked the emperor will man be resurrected? From the luz of the spinal column answered the rabbi How can you prove it? asked Hadrian In reply Rabbi Joshua brought that bone before the king and subjected it to the following tests He threw it into the fire but it was not consumed He then put it into water but it would not soften He tried to crush it with a grindstone but failed Finally he hammered it on an anvil and although both the hammer and the anvil broke the bone remained intact The luz referred to represents the sacrum—or possibly the coccyx which being the indestructible nucleus of resurrection was accepted by Mahommedan as well as Christian anatomists and theologians as the sacred bone and was often referred to in the Middle Ages as Jew bone This legend of the resurrection bone which was accepted by Vesrroes is true is based on the 20th verse of Psalm XXXIV the second part of which is capable of being translated in two ways The Authorized Version translates it as not one of the [illegible] the bones of the righteous is broken but the translation of the Revised Version —namely one of them could not be broken — equally admissible The very pious Jews bow down in the course of certain portions of the prayer until the lumbar spine bends on the sacrum in order to emphasize resurrection

Similar legends about the indestructibility of different parts of the body are found in heathen antiquity The right thumb of King Pyrrhus is recorded by Pliny (vii 7) as having been supposed to be indestructible by fire (hunc cremari cum reliquo corpore non potuisse traditum) —I am etc

Obituary

SIR THOMAS LEGGE C B E M D

Late Senior Medical Inspector of Factories Home Office

We much regret to announce the death on May 7th at Warlingham of Sir Thomas Legge medical adviser to the Trades Union Council and for many years senior medical inspector of factories at the Home Office His wide knowledge of occupational diseases and industrial hygiene was always at the disposal of any organization or person seeking expert information and guidance

Thomas Morison Legge youngest son of the Rev James Legge D D LL D first professor of Chinese in the University of Oxford was born at Hong Kong on January 6th 1863 From Magdalen College School he went to Trinity College Oxford and thence to St Bartholomew's Hospital He graduated M B B Ch in 1890 obtained the D P H in 1893 and proceeded M D in the following year after a period of post-graduate study in Vienna He served as secretary of the Royal Commission on Tuberculosis 1890–5 and was then appointed senior medical inspector of factories At the Annual Meeting of the British Medical Association in 1902 he was honorary secretary of the Section of Industrial Hygiene and Diseases of Occupation and vice-president of the same Section in 1905 In that year he gave the Milroy Lectures before the Royal College of Physicians taking as his subject industrial anthrax The rapid development of the work of the Factory Department of the Home Office that followed the passing of the Workmen's Compensation Act of 1906 provided Legge with a widening field for his abundant energy In the course of his duties he travelled much and sat on many committees dealing with compensation for industrial diseases anthrax painters' colic buildings and tuberculosis in cattle

His published writings included a paper on public health in European capitals (1896) reports on cataract in glass workers (1908) and on epithelomata as cancer in relation to the manufacture of patent fuels (1911) He was also joint author with Sir Kenneth Goadby of *Lead Poisoning and Lead Absorption* and translator and editor of Rambousek's *Industrial Poisoning* The Royal College of Physicians awarded him the Bisset Hawkins medal in 1923 for his work during the preceding ten years promoting public health He was created C B E in 1918 and received the honour of knighthood on the occasion of 1925 In 1927 he delivered a Cantor Lecture on the teaching of industrial medicine and in the two following years the William Withering Memorial Lecture at Birmingham University and the Shaw Lecture to the Royal Society of Arts He also gave the Lettsomian Lectures at Boston and the Cartwright Lectures at Bradford and was lecturer on factory law at the universities of Manchester and on industrial poisons at the London School of Hygiene and Tropical Medicine

Sir Thomas Legge represented the British Government on the Advisory Hygiene Commission of the International Labour Office at Geneva and took an active part in drafting the International Convention which forbade the use of white lead in the internal painting of buildings. When in 1926 the British Government issued regulations applying the term of the Convention to this country, he resigned his appointment at the Home Office as a protest against the inadequacy of the regulations. Three years later he accepted an invitation to become medical adviser to the newly-formed Insurances section of the Trade Union Congress. For some time past he had been a valued occasional contributor to the *British Medical Journal* on matters relating to occupational diseases and factory hygiene and on the international aspects of workmen's compensation. He was a man of charming personality with a cultivated mind and a deep sense of social responsibility.

We have to announce the death on April 11th of *Dr Harry Leeson Ivor*. He was the son of a naval surgeon and he was born at Cape Town in 1867. After studying at the Bedford General Laboratories for a year he went in 1885 to St Bartholomew's Hospital where he took his M.R.C.S. and L.R.C.P. He obtained the M.D. degree of Durham in 1907. After acting as assistant at Hetton he practised at Jedburgh for over twenty years. In 1915 he was appointed the 4th Yorkshire Battalion to France and in their first engagement at Ypres distinguished himself by gallant conduct in saving fifteen wounded men from a burning farmhouse or cellar. His name is believed to have been three times put up for the V.C. After being severely wounded and invalided home he was soon appointed S.M.O. No. 2 Section Tynemouth Garrison with headquarters at Tynemouth. After the war he took up appointments with various collieries in Durham and Yorkshire as compensation doctor where he gained the confidence and esteem of both the companies and the miners. He was a keen sportsman an expert on bird culture and a prominent Freemason.

The death occurred on April 28th at his residence in Bristol Road Edgbaston Birmingham of Dr Richard Jeffrie Bankes a well-known practitioner in Birmingham for nearly forty years though he never took any part in public life. He built up a large private practice and was much loved and respected by his patients to whom his professional services were most willingly given. He obtained the triple qualification of the Conjoint Board of Scotland in 1892 and was 65 years of age. He leaves a widow and two daughters.

Medico-Legal

MEDICAL MAN AWARDED DAMAGES FOR PERSONAL INJURY

In the King's Bench Division before Mr Justice Swift and a common jury on May 3rd Dr Frances Joyce of Camberwell claimed damages for personal injuries against Mr Stanley L. Wilson of Kingston on Thames. The plaintiff's case was that in July last while riding his bicycle in Camberwell a motor car driven by defendant collided with him with the result that he was thrown from his bicycle and received a lacerated wound from elbow to wrist tearing the ulnar nerve and affecting the use of his hand in the performance of surgical operations. The defendant denied negligence and alleged that plaintiff contributed to the accident by failing to keep a proper look-out. The jury found for the plaintiff and awarded him £5 000 damages and £244 special damages. Judgement for Dr Joyce was entered accordingly with costs.

On the following day Mr Justice Swift granted leave of execution pending consideration of an appeal the ground of appeal being that the damages were excessive and against the weight of evidence. The judge said that he would not grant a stay except to give the defendant an opportunity of inquiring of the Court of Appeal whether that court thought the damages were excessive. He himself did not think they were having in mind that the plaintiff was a professional man who practice depended on the use of his hands and the appearance he presented to his patients. The stay was granted on condition that half the amount of the damages was paid to Dr Joyce at once the remainder with the special damages to be paid into court and await the decision of the Court of Appeal. The appeal said the judge must be entered within seven days or execution would be unrestrained and he wished to make it quite plain that £2 500 would not be recovered in any event.

On May 10th the Court of Appeal (Lords Justices Scrutton Greer and Slesser) varied the terms on which Mr Justice Swift had granted stay of execution pending appeal. The Court directed that £500 should be paid to Dr Joyce without any conditions as to its non-recovery and that the balance of the sum awarded as damages be paid into Court within fourteen days.

HIGH COURT DECISION AGAINST OSTEOPATH

On May 11th a Divisional Court consisting of the Lord Chief Justice Mr Justice Avory and Mr Justice Macnaghten unanimously allowed an appeal on behalf of the Medical Defence Union against a rule by the Marylebone magistrate that an osteopath who described himself as an osteopathic physician and surgeon had not committed an offence under the Medical Act 1858. The magistrate had dismissed a summons brought by the Union against Mr A. E. Shakesby for a letter and osteopath of Dorset Square N.W. for wilfully and falsely assuming the titles physician and surgeon. According to the evidence given at the police court Mr Shakesby had upon his doorplate Professor A. E. Shakesby D.O. (London) Bone-setter Osteopathic Physician and Surgeon.

The Divisional Court held that the case must go back to the magistrate with a direction to convict and the Union was allowed the costs of the appeal.

A report of the proceedings with the judgements of the Lord Chief Justice and Mr Justice Avory will be given in our next issue.

Centenary Meeting—Oversea Visitors

All overseas delegates and guests and other members from overseas intending to take part in the Centenary Meeting of the British Medical Association next July who desire hospitality for themselves (and for their wives if accompanying them) should communicate immediately with Sir Crisp English K.C.M.G. 82 Brook Street London W.1.

Masonic Welcome

The Motherland Lodge 3861 is arranging a special meeting on Monday July 25th to welcome as its guests medical Freemasons on their visit in connexion with the Centenary Meeting. Brethren from overseas who wish to be present should write (or cable) as soon as possible to the secretary of the Motherland Lodge Mr Arnold West (Trafalgar Buildings 1 Charing Cross W.C.2—cable address Bullewest London) giving details of Lodge, Masonic rank etc.

Universities and Colleges

UNIVERSITY OF DUBLIN

There was an error in the announcement under this heading last week. The degrees of M.A. and M.D. have been conferred on Dr Edward Bethel Solomons. His uncle Dr Bethel Solomons Master of the Rotunda took the M.D. in 1912.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

At a quarterly meeting of the Royal College of Physicians held on May 3rd with the President Dr Robert Thin in the chair Dr William Lindsay Lamb (Aberdeen) took his seat as a Fellow and Dr John McIntosh Morgan M.C. (Dundee) was elected a Fellow.

Sir Norman Purvis Walker was elected a representative of the College on the Committee of Management of the Triple

Qualification and Dr A Fergus Howat was elected a trustee of the College

Edith Kate Dawson M A M B was awarded the Lister Fellowship for original research

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

At the monthly business meeting of the College held on May 6th James Michael O Donovan M D N U I was admitted to the Fellowship and S P Bhiwandker was admitted to the Licence in Midwifery

The following successful candidates at the Conjoint Final Examination with the Royal College of Surgeons in Ireland were admitted to the Licences in Medicine and Midwifery Bridget M M Dunlevy P Hughes Thirza M P Johnson D Kinsella

The Services

The Royal Naval Volunteer Reserve Officers Decoration has been awarded to Surgeon Commander I C D Irvine R N V R

NORTH WEST FRONTIER OPERATIONS

The names of Major H C Godding M C R A M C and Third Class Assistant Surgeon J Edwards and Sub Assistant Surgeons S Alexander and Harwant Singh of the Indian Medical Department are included in the list mentioned in a dispatch by General Sir Philip Chetwood G C B K C M G D S O Commander in Chief in India for distinguished services in connexion with the military operations on the North West Frontier of India from October 1930 to March 1931

DEATHS IN THE SERVICES

Lieut Colonel Cecil Willoughby Johnson R A M C (ret) died on March 18th aged 74 He was born at Agra on October 11th 1857 and was educated at Edinburgh University where he graduated M B and C M in 1882 Entering the Army as surgeon on January 31st 1885 he became lieutenant colonel after twenty years service and retired on October 11th 1912 He served in the Sudan in 1885-6 in the Frontier Field Force and was present at the action of Giniss receiving the Egyptian medal and the Khedive's bronze star on the North West Frontier of India in 1897-8 gaining the Frontier medal with a clasp and throughout the South African war 1899-1902 when he took part in operations in Natal the Transvaal the Orange River Colony and Cape Colony and was present at the relief of Ladysmith including the actions of Colenso Vaal Krantz Tugela Heights and Pieter's Hill and subsequently in actions at Reit Vlei Belfast and Rundam and received the Queen's medal with five clasps and the King's medal with two clasps After his retirement he was re employed in the war of 1914-18

Major General Bruce Morland Skinner C B C M G late R A M C died suddenly at Colchester on May 3rd aged 74 He was born in India on April 5th 1858 was educated at St George's and took the M R C S in 1879 and the L R C P Ld in 1881 Entering the Army as surgeon on July 29th 1882 he became lieutenant colonel after twenty years service colonel on May 4th 1912 and temporary surgeon general in 1916 he retired on December 26th 1917 and was granted the honorary rank of major general on April 26th 1918 He was secretary to the Medical Advisory and Nursing Boards at the War Office from 1902 to 1907 commandant and director of medical studies at the Royal Army Medical College from August 15th 1912 to August 4th 1914 was given the M V O in 1906 and was honorary surgeon to the Viceroy of India in 1910-11 He served in the campaign on the North West Frontier of India in 1897-8 gaining the Frontier medal with a clasp in the South African war from 1899 to 1901 when he served in the Orange Free State as P M O of a Division and took part in the relief of Kimberley and in the actions at Paardeberg Poplar Grove and Driefontein was mentioned in dispatches in the *London Gazette* of April 10th 1901 and received the Queen's medal with five clasps and in the war of 1914-18 when he served as D M S of an army and as deputy inspector of medical services in 1918-19 was five times mentioned in dispatches—in the *London Gazette* of January 1st 1916 January 4th 1917 May 29th 1917 December 24th 1917 and May 25th 1918—and received the C M G in 1916 and the C B in 1918 He was the author of many papers in scientific journals on the geology of the Indian Frontier and of South Africa and also on plague In 1884 he married Monica daughter of Henry Whiteside who survives him and had three sons and one daughter

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

Parliament has adjourned over Whitsuntide The House of Commons rose on May 13th and will resume on May 23rd It has this week read the Limitation Bill and the National Health Insurance Bill a second time

On May 9th the Epsom College Bill passed through committee of the House of Commons without amendment and was read the third time

Committee on Medical Branches of the Services

Dr ELLIOT replying on May 10th to Mr Liddall said that it was not yet possible to forecast when the inquiry which was being conducted by the Committee on Medical and Dental Branches of the Defence Services might be completed May 19th 1931 would be completed The cost of the committee to date was about £200 Mr LIDDALL asked if twelve months was not long enough for the committee to produce a definite report Dr ELLIOT said that the committee's work was suspended for some time during the crisis last autumn but it was now sitting again

Maternity and Infant Welfare

Sir HILTON YOUNG told Mr Parkinson on May 5th that the comparative figures for 1930 and 1931 showing the provision made for the care of mothers and babies by local authorities and voluntary agencies in England and Wales were

Services	1930	1931
Ante natal clinics		
Local authorities	978	1,014
Voluntary agencies	194	196
Maternity homes and hospitals		
Provided by local authorities	66	63
Provided by voluntary agencies	144	138
Number of beds provided by local authorities	1,316	1,322
Number of beds provided by voluntary agencies	219	191
Institutions transferred to local authorities under Part I of Local Government Act 1929 which include maternity wards	5	
Number of beds in the wards	395	386
Nurses employed for the nursing of expectant mothers and children under 5 years of age suffering from infectious or other illness	204	227
Convalescent homes for expectant and nursing mothers or children under 5 years of age		
Provided by local authorities	17	14
Provided by voluntary agencies	1	
Number of beds provided by local authorities	—	—
Number of beds provided by voluntary agencies	43	43
Homes for mothers and babies		
Provided by local authorities	6	6
Provided by voluntary agencies	11	
Number of beds provided by local authorities	18	18
Number of beds provided by voluntary agencies	7	26

Dumping of Refuse

On May 5th in the Standing Committee which was considering the Town and Country Planning Bill Captain ACLAND TROYTE moved a new clause to the effect that refuse from one county should not be dumped in a part of another county save with the consent of the council of that county Sir HENRY JACKSON said that while it was a matter of town planning but could be dealt with by amendment of the Public Health Act 1875 A departmental committee had reported that it was possible to dump dust to

give no offence and that there were practical difficulties in giving county councils power to exclude refuse For London boroughs the only alternatives were to dump the refuse outside the borough or to take it out to sea and the latter course was extremely expensive Sir HILTON YOUNG replied that the object of the clause was to prevent pollution with the object of the clause but could not accept it as it would create a crisis in administration He had the subject under consideration and hoped to find some solution which would reconcile the two points of view He gave no undertaking to bring in legislation The things were far better settled by agreement between the parties After further debate the dumping of Shoeburyness rubbish in Derbyshire and of London rubbish in Hertfordshire Essex and Kent the proposal was lost by 14 votes to 12

Government Commissions still at Work

Dr ESSLEMONT told Mr JOWITT on May 5th that among commissions and committees appointed since 1929 and still at work were

Inquiries whether (1) pecuniary compensation and (2) pensions in course of payment under mule spinners' certificates should be included in the Schedule of Industrial Diseases to which section 43 of the Workmen's Compensation Act 1925 applied A further interim report on this was not ready

Inquiries into the causes of the shortage of officers and nurses in the local and general branches of the three Defence Services and into general recommendations for remedies were not

Inquiries whether the enactments applying to England and Wales should be consolidated with (1) local enactments of local governments and (2) matters relating to public health should be grouped in consolidating legislation

Inquiries into the working of the Acts as to compensation and the operation of articles of food order Bill in full

Road Accidents and Ventilation of the Mersey Tunnel

On May 6th Mr PYBUS when opening a debate on the Ministry of Transport paid tribute to the injury and loss of life on the highways of the United Kingdom He said public opinion was awakened to the appalling record Mr PYBUS also said that it was very rare from every hospital in the country that people injured on the road were taken in sometimes for weeks or even months but the hospitals received no remuneration for the expense incurred The Minister should consider that

Mr RHYS DAVIES said it was curious that the Automobile Association could not take up the question of payment to hospitals in respect of its own members The association paid the legal charges of its members and should contribute something to the medical and hospital charges as well

Mr PYBUS in his reply did not refer to hospitals He mentioned that difficulties had been found in ventilating the Mersey Tunnel The Government had given £2 500 000 as a grant to that tunnel and could not increase their liability

Cerebro spinal Fever at Windsor—Mr DUFF COOPER replying to Mr Groves on May 9th said that no primary vaccination during service in the Army had been performed on any of the nine cases of cerebro spinal fever which had occurred this year at Windsor The most recent revaccination was in June on December 16th last on a case which occurred one driven last Five of the cases had been inoculated that be was three and one case was immunized against wound from elbow 1932 affecting the use of his operations The defendant denied that plaintiff contributed to the accident by not keeping a proper look out The jury found negligence and awarded him £5 000 damages and £24 for special treatment Judgement for Dr Joyce was entered accordingly

On the following day Mr Justice Swift granted a stay of execution pending consideration of an appeal the ground of appeal being that the damages were excessive and against the weight of evidence The judge said that he would not grant a stay except to give the defendant an opportunity of inquiring of the Court of Appeal whether that court thought the damages were excessive He himself did not think they

of sleepy sickness was paralysed and crippled and who instead of being sent to a suitable home was detained at Rampton an institution for mental defectives where he suffered ill treatment which necessitated the removal of his right eye and whether he would cause an inquiry to be made into the conduct of this institution to ensure that in future only cases in which radical mental defect was present were kept there Mr L BROWN replied that the attention of the *Minister of Health had been called to this case* Harold Lee *was feeble minded and partially paralysed* He was sent in the first instance to a residential special school for mental *defectives his mother having stated that he was dangerous and beyond her control* Owing to his violent behaviour he could not be retained at the special school and was ultimately sent to the special block for children at Rampton In May last year the patient on his own admission dislocated his own right eye and this injury *necessitated* its removal There was no foundation for the allegation that this was due to ill treatment The circumstances of the case had been very fully examined and the Minister of Health did not consider that any further inquiry was called for If Dr Williams desired any further information the Minister would be glad if he would communicate with him

Medical Profession and Climatology—Replying on May 5th to Mr MCENTEE Sir HILTON YOUNG said that attention was paid to the subject of climatology by the medical profession The subject was included in the course for diplomas in *public health* The importance of facilities for treatment at health resorts was dealt with in a report on chronic rheumatism issued by his Department

Approved Societies without Surplus—In answer to Mr BUCHANAN on May 4th Mr L BROWN said he had invited certain approved societies who had no surplus funds under the National Health Insurance Act to submit a written statement of the representations they wished to make as he did not feel that their proposed deputation would be justified

Experiments on Animals—On May 10th Sir H SAMUEL informed Mr GROVES that the twelve experiments performed *on animals under Certificate A without anaesthetics during* 1930 at the place No 222 registered for the purpose were the feeding of animals for the *purpose of tests* The registered premises *were the Research* [illegible] 149 and J and J *Colman's Carrow Works* [illegible] 119 *experimenters were experienced research* [illegible] 3 015 158 165

A sessional meeting of the Royal Sanitary Institute will be held in the Guildhall Gloucester on Friday May 27th when discussions will take place on slum clearance to be introduced by Dr R B Berry medical officer of health Gloucester and on technical methods and devices in connexion with the pasteurization of milk to be introduced by Sir Weldon Dalrymple Champneys Bt medical officer Ministry of Health and Dr R Schigman Dr George F Buchan will occupy the chair

At the meeting of the Royal Microscopical Society to be held on Wednesday next May 18th in the B M A House Tavistock Square at 5 30 p m Professor Hamilton Hartridge will describe microscopical projectors for making drawings and for lecture purposes and Drs P R Peacock and Woodhouse Price will discuss the cinematographic examination of serial sections as an aid to histology

The next monthly clinical meeting for medical practitioners at the Hospital for Epilepsy and Paralysis Maida Vale W will be held on Thursday May 26th at 3 o'clock when Dr Douglas McAlpine will demonstrate Tea will be provided Those intending to be present are asked to send a card to the secretary

The fifth Malcolm Morris Memorial Lecture under the Chadwick Trust will be given on Monday May 23rd at the Royal Society of Arts John Street Adelphi W C by Sir Ernest Graham Little who has chosen as his subject Dermatology as an outpost of medicine The chair will be taken by Sir Harold Morris K C at 5 15 p m

A Mid Wales spa conference arranged by the British Health Resorts Association will be held at Llandrindod Wells from May 20th to 23rd by invitation of the Urban District Council and the Medical Society of Llandrindod Wells The business sessions will be held at the Pump House Hotel on Saturday May 21st In the morning Sir Humphry Rolleston will take the chair and in the afternoon Sir William Willcox

The Royal Medico Psychological Association announces that an examination for the Gaskell gold medal prize and the examination for the certificate in psychological medicine will take place at the Maudsley Hospital Denmark Hill S E on May 27th and 28th at 10 a m There is no fee for entrance to the Gaskell prize examination Applications for entry to either examination should be sent to the registrar Dr D F Rambaut St Andrew's Hospital Northampton before May 20th

The council of Epsom College Royal Medical Foundation will shortly award a Prince pension of £30 a year to a duly qualified medical man of not less than 55 years of age If the candidate is a single man or a widower his income independent of any allowance from the College or from the Royal Medical Benevolent Fund must not exceed £100 per annum If he is married the combined income of himself and his wife must not exceed £150 per annum Forms of application should be obtained forthwith from the secretary Epsom College 49 Bedford Square W C 1 and must be returned completed to him not later than June 15th 1932

The Irish Hospitals Nursing and Midwifery Conference will be held in Dublin at the Mansion House and the Institution of Civil Engineers of Ireland on May 16th 17th and 18th The addresses will deal with specialized nursing mental nursing maternity and child welfare midwifery public health tuberculosis the clinical domestic and financial administration of hospitals and certain medical topics Full details of the sessions of the conference and the official visits may be obtained from the secretary 70 Lower Leeson Street Dublin

A national conference on maternity and child welfare will be held in the Council Chamber of the Guildhall London on July 4th 5th and 6th It will be preceded by a clinical week end for medical practitioners organized on behalf of the National Council for Maternity and Child Welfare and its constituent bodies by the National Association for the Prevention of Infant Mortality in co operation with the maternity and child welfare group of the Society of Medical Officers of Health Particulars may be obtained in due course from Miss Halford Carnegie House 117 Piccadilly W 1

The seventeenth French Congress of Legal Medicine will be held at the Medico Legal Institute Paris from May 23rd to 25th under the presidency of Dr Bayart of Lille when papers will be read on lesions of the liver in drowning by Dr L Martin of Lyons traumatic Parkinsonian syndromes by Drs Naville and Monakow of Geneva and psychanalysis in legal medicine by Dr Genil Perrin of Paris

Sir Herbert Samuel will deliver his presidential address before the British Institute of Philosophy entitled Philosophy and the ordinary man on Wednesday May 25th at 8 30 p m at University College Gower Street W C Tickets can be obtained by the general public from the Director of Studies University Hall 14 Gordon Square W C 1

The annual report for 1931 of the Ross Institute and Hospital for Tropical Diseases Putney Heath S W 15 contains an account of the way in which the Indian branch is actively promoting the eradication of malaria on tea planting estates by expert investigation of the local causes of infection and their effective treatment Research work at the Institute during the year has included the study of diseases due to fungi the bacterial agents in intestinal diseases and the preparation of serums against certain specific organisms Visits have been paid by delegates from the Institute to Northern Rhodesia in connexion with inquiries into the biology of mosquito and the value of certain new antimalarial drugs) East Africa Italy Albania Holland and the Fen districts of England

Dr Hugh S Cumming has been reappointed surgeon general of the United States Public Health Service for another four years

Letters. Notes. and Answers

All communications in regard to editorial business should be addressed to **The EDITOR British Medical Journal British Medical Association House Tavistock Square W C 1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated Correspondents who wish to be informed that their communication should have been safely received with their names not necessarily for publication

Authors desiring REPRINTS of their articles should inform the *British Medical Journal* when returning proof

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are MUSEUM [illegible] and 9864 (internal exchange four lines)

The **TELEGRAPHIC ADDRESSES** are

QUERIES AND ANSWERS

Cause of Urethral Discharge

Dr E C March (Reading) writes Can any of our readers throw some light on the following problem I have been called in to see a young married man who complains briefly of the following symptoms He had an attack of rheumatism or meningism in the [illegible] night four subsequently a volume of [illegible] of the right leg and even by the [illegible] considerable fluid in the [illegible] was raised a little On the [illegible] a urethral discharge which [illegible] next day thus preventing [illegible] discharge had been [illegible] accompanied by pain on [illegible] obviously honest statement from [illegible] was not infected and from which [illegible] I am convinced that the condition was [illegible] What was it

ign is the relatively frequent escape of the apices and especially the localizing of the lesions in the middle portions near the hilus of both lungs All specific treatment (mercury arsenic or bismuth) is rapidly efficacious in pulmonary syphilis more particularly in recent or undiagnosed and untreated cases Potassium iodide should be used only in the chronic form in which pulmonary sclerosis predominates The latter condition is less amenable to treatment hence the need for an early correct diagnosis

444 Auricular Fibrillation

D McKenzie and B M Baker jun (*Amer Journ Med Sci* January 1932 p 35) have observed 575 consecutive patients suffering from auricular fibrillation confirmed by electrocardiogram Of the number in 34 per cent the condition was of rheumatic origin while in 48 per cent either arteriosclerosis or hypertension or both appeared to be the aetiological factor Hyperthyroidism and syphilis were believed to account for 8 per cent and 3 per cent respectively The higher incidence of auricular fibrillation occurring in the sixth decade instance are very much below that of 12 but the authors have described two patients in whom the arrhythmia was recorded The author comments on the rarity of auricular fibrillation in association with syphilitic heart disease of the total group of 575 patients syphilis was recorded as the aetiological factor in only eight It was found that auricular fibrillation may be induced by digitalis therapy chiefly when individual idiosyncrasy or failure to prevent the arrhythmia in the ventricle normally by concomitant blockade is responsible for digitalis intoxication does preceding it A study of auricular fibrillation mainly from the standpoint of prognosis and treatment has also been made by W D Stroud I B Lawson and J V Klauder (*ibid* p 48) who have observed 251 patients They found that while the average age of onset in the rheumatic group was 30 years that of the non rheumatic group was 50 years Analysis of seventy seven cases showed that the prognosis was especially poor if fibrillation started before the age of 20 years in even such instances the subsequent duration of life averaged only one year When the arrhythmia set in after the age of 40 the average duration of life was five years Restoration of normal rhythm by quinidine occurred in two thirds of the sixty six patients so treated but the authors found that even if normal rhythm was restored the duration of life was only about one year longer than in those fibrillators not receiving quinidine

Surgery

445 Preliminary Pneumothorax in Intrathoracic Surgery

J Arci (*Bull Acad de Méd*, February 9th 1932 p 212) has found as the result of experimental and operative experience that a preliminary pneumothorax performed by degrees according to the tolerance of the patient contributes most effectively to the success of intrathoracic operations He insists on the importance of studying the radiographic appearances at intervals of a few days, to estimate whether atelectasis is sufficiently complete and, in the case of tumours to enable really accurate diagnosis to be made, he has found that nitrogen is the best gas for use in replacement Performing a preliminary pneumothorax, he has undertaken a number of experimental operations on sheep, thoracotomy even when an extensive opening has been made, was well tolerated Operations such as partial or complete lobectomy produced signs of respiratory embarrassment and in the case of a very wide thoracotomy resulted in the death of the animal with signs of acidosis and asphyxia The most successful operation was that of lobectomy, performed after resection of a single rib and the use of retractors as in the operation on human subjects Protection of the collapsed lung during the operation, by swabs moistened with artificial serum minimizes shock, and prevents mishaps attendant on re-expansion Provided that this precaution is taken, and that handling of the lung is minimal asphyxial accidents are avoided A preliminary pneumothorax followed by thoracotomy with resection of a single rib is the ideal procedure for approach according to this author

446 Acute Pancreatitis with Impacted Calculus

R Reding P La Haye and Fr Drome (*Le Scalpel* February 13th, 1932 p 207) report the case of a woman 33 years old admitted into hospital with severe epigastric pain of three hours duration—a girdle pain, radiating to the right hypochondrium and the back but not to the shoulder She had vomited bile with no relief of the symptoms There was no history of previous illnesses On examination the temperature was 99° F and the pulse 62 regular and small The heart and lungs were healthy, and the abdomen was soft but with tenderness in the epigastrium and over the gall bladder The bowels had moved twice the urine was rich in bile pigment, and there was a slight leucocytosis Nausea was present but no further vomiting occurred Morphine and hot fomentations did not relieve the pain After six hours the pulse rose to 102 the abdomen became tympanitic and the patient presented signs of collapse Vaginal examination was negative except for a prolapsed ovary in the pouch of Douglas and the abdomen was opened in the mid line below the umbilicus The peritoneal fluid was blood stained but the appendix and uterine appendages were healthy The abdomen was closed and opened again in the mid line above the umbilicus The gall bladder was found to be distended and full of calculi one being palpated in the bile duct and another in the ampulla of Vater they were both expressed into the duodenum The lesser sac was opened and the pancreas explored On the anterior surface of its body was a vesicle measuring 2 inches by 1 inch This disappeared after haemorrhage from a blood vessel in the lesser sac The body of the pancreas was soft on palpation but the head was indurated The opening into the lesser sac was closed without drainage Cholecystostomy was performed the gall bladder being emptied of about fifty calculi and drained The subsequent progress of the patient was normal

447 Intussusception

H J Shelley (*Arch of Surg* February 1932 p 318) states that the treatment for intussusception is primarily surgical the procedure being determined by the state of the bowel found at the time of operation An early diagnosis is of the greatest importance and ensures a relatively simple operation while the patient is in a good condition The disorder can often be discovered by placing the right index finger in the child's rectum and the left hand on the abdomen with the child in a sitting position If a tumour is present this will usually drop down between the hands of the examiner In cases of doubtful diagnosis x-ray examination will be of value and also a barium enema to show the site of the obstruction Intussusception may be reduced also by the use of pressure enemas or air insufflation, but this should be followed by abdominal exploration to ensure that reduction is complete and that no gangrene tumour or perforation is present Most cases of intussusception are easily reduced by careful manipulation, but if this is not possible the bowel may be incised at the point of invagination, and the intussusception be reduced Alternatively enterostomy above the lesion which may be followed by spontaneous reduction, or a lateral anastomosis between the afferent and efferent loops of intestine with subsequent fixation invagination has proved satisfactory In cases of gangrenous intussusception a resection followed by a lateral anastomosis is the ideal operation but if the condition of the patient is not good enough to allow this a double barrel resection is a life saving procedure and must be followed by an extra abdominal ileostomy When a gangrenous intussusception is complicated by perforation the quickest procedure must be adopted to remove the damaged intestine and relieve the obstruction The modified Mikulicz operation followed by adequate drainage is the operation of choice

in these cases. Pre-operative treatment should include the administration of water, salt and dextrose by hypodermoclysis or infusion. A case is reported of a child aged 15 months in whom the intussusception had perforated and was irreducible and gangrenous. A modified Mikulicz resection with drainage of the peritoneal cavity was performed and the child made a good recovery.

448 Prevention of Peritoneal Adhesions

A. OCHSNER and E. CARSIDE (*Surg. Gynecol. and Obstet.* February 15th 1932, p. 338) point out that though post-operative peritoneal adhesions are protective in the presence of infection they may mar the outcome of an otherwise successful operation. Normally peritoneal adhesions disappear after completing their useful-ness, the fibrin being digested by a proteolytic ferment from the polymorphonuclear leucocytes. If the fibrin is not removed it becomes organized and replaced by fibrous tissue. Fibrous adhesions may occur especially in subjects with an inherent tendency to fibrous tissue development. In an investigation covering a period of five years the present authors have tested the efficacy of digestive ferments in preventing peritoneal adhesions. Solutions of trypsin and papain (a vegetable digestive ferment) were extensively tried, and the latter proved to be by far the most efficacious. Trypsin was used in one of 11 clinical cases but did not prevent the recurrence of adhesions. The other cases in which papain was employed have remained symptom-free for from six months to five years. From their clinical and experimental observations Ochsner and Garside are convinced that the intraperitoneal injection of papain solution is entirely without danger.

449 Staphylococcal Septicaemia

G. MARAÑON and MORROS (*Arch. de med. cir. y esp.* March 5th 1932, p. 189), who record an illustrative case, state that staphylococcal septicaemia is relatively rare, especially when compared with streptococcal infection, forming only 6 per cent. of all septicaemias according to Simmonds. Metastases are most frequently found in the thorax, kidneys and perirenal tissue. The prognosis mainly depends on the patient's resistance. The present case was that of a man aged 24, debilitated by syphilis, gonorrhœa and soft chancre, who developed staphylococcal septicaemia secondary to a boil on the neck. An empyema ensued and a pure culture of staphylococci was obtained from the pus. Death followed a few hours after pleurotomy. At the post-mortem examination a perirenal abscess was found together with an abscess in the substance of the kidney. The other organs were normal.

450 Acute Pancreatitis

C. R. JONES (*Amer. Journ. of Surg.* March 1932, p. 510) divides acute pancreatitis into two varieties, the hæmorrhagic which may result in gangrene, and the suppurative type found in the infectious diseases which cause abscesses in and about the pancreas. There may also be cases of bacterial invasion of the pancreas giving rise to abdominal symptoms. The gangrenous type of pancreatitis may be caused by trauma, apoplexy or by over-distension under pressure by bile or other fluid causing a backward pressure and distending the gland so as to bring about some slight solution of continuity in the blood vessels. Disease of the pancreas may be secondary to diseases of the biliary tract. The causes of pancreatic abscess may be extending inflammation as ending in inflammation, hæmorrhagic necrosis, an infectious disease or hæmatogenous. Peripancreatitis may exist as an extension from perigastritis or duodenitis or other adjacent inflammations. Symptoms of the gangrenous type of pancreatitis are vomiting, intense pain, profuse sweating and possibly swelling and tenderness. The skin is pale and dusky. Death may occur from shock, collapse or in operation and a post-mortem examination may disclose evidence of fat necrosis. Treatment in all forms of acute pancreatitis must be surgical and in the hæmorrhagic necrotic type should be immediate. Even when the operation is more radical with partial or total abscess-cavity resection, a better chance of recovery is undertaken as soon as possible. A case is reported which a robust man aged 40 was [illegible] with severe abdominal pain. There was a history of indefinite pain in the epigastrium for two years. Laparotomy disclosed blood-stained serum under the liver and round the gall-bladder and duodenum. The head of the pancreas was hæmorrhagic and œdematous. The peritoneum was opened over the head and right half of the pancreas and drainage was instituted. The patient made a good recovery and remains in excellent health. Emphasis is laid on the importance of operation at the earliest possible moment.

Therapeutics

451 Combined Antivirus and Vaccine Treatment of Acne Vulgaris

A. IVAKTIN (*Russ. med. Woch.* February 5th 1932, p. 173) has prepared an autogenous vaccine in cases of acne vulgaris by inoculating the contents of a number of pustules on agar or sugar agar and making a control of the resulting cultures. He has also prepared an antivirus by Besredka's method. Increasing doses of the vaccine were given every four or five days, half of each dose was injected in divided portions intracutaneously and half subcutaneously, not more than 0·2 c.cm. of the intracutaneous dose being introduced at the same time. Local compresses of the antivirus were applied after the vaccine injections had been continued for twelve to fifteen days. Before the antivirus was applied the skin was washed with warm water and cleansed with ether. As an alternative to the compresses the antivirus may be applied as an ointment, one part of antivirus to two parts of ointment consisting of white vaseline and lanoline (1:2) or eucerinum anhydricum may be used as a base. Very satisfactory results were obtained from the combined treatment in a number of cases, provided that the injections were continued long enough, some patients required ten to fifteen injections, others as many as thirty to forty.

452 Serotherapy in Tularæmia

I. JOSHAY (*Journ. Amer. Med. Assoc.* January 23rd 1932, p. 552) treated ten cases of tularæmia with a specific serum prepared from a goat inoculated with formaldehyde suspensions of *B. tularense*. Doses of 10 c.cm. were usually given intravenously on both the first and the second day in hospital. No reaction occurred. Nine patients showed abrupt cessation of fever, malaise, arthralgia and myalgia forty-eight hours after the second injection and rapid reduction in size of the affected lymph glands, none of which suppurated. In one patient who was moribund on admission he considered the serum therefore is considered by Joshay to be a prompt and reliable treatment for tularæmia.

453 Intravenous Injection of Anti-gonococcal Vaccine

J. GATE, P. CUILLERET and C. L. POYET (*Bull. Soc. Franç. de Derm. et de Syph.* January 1932, p. [illegible]) describe the effects of intravenous injection of anti-gonococcal vaccine given in order to [illegible]. A man aged 26, who was admitted with [illegible] rheumatic orchi-epididymitis of five days' duration. The initial urethritis had occurred about [illegible] previously. On admission it was [illegible] therapeutic injection of gonococcal vaccine was [illegible] for the treatment of the orchitis there was given a series of hypodermic injections of [illegible] commencing with 0·5 c.cm. and [illegible] 2 c.cm. on alternate days. The [illegible] doses which were well borne, [illegible] painful local inflammatory reaction. The eighth dose, 2 c.cm., was given slowly. When the eighth dose, 2 c.cm., was given

0·5 c.cm. was injected by mistake into a vein, the remainder of the dose being given hypodermically. Ten minutes later the patient exhibited severe symptoms of shock—acute dyspnœa with rapid breathing, intense cyanosis and syncope with extreme pallor. The pulse could not be counted and he sweated profusely. He was relieved quickly by diffusible stimulants and inhalations of oxygen. He recovered consciousness but complained of headache and exhaustion. In a few hours the temperature rose to 102°2. Next day he had recovered except for a slight headache. The orchitis subsided in a few days without further vaccine treatment. The authors indicate two facts as meriting attention: the severity of the shock following the intravenous injection of vaccine and the rapid disappearance of the orchi-epididymitis, which seemed to melt away under what they believe to have been the anaphylactic shock. The fact of the patient having been sensitized by the previous injections appears to explain the severity of the shock. This had in spite the therapeutic action due to the production of an antigen.

454 The Administration of Anti-diphtheritic Serum

R. DEBRÉ, G. RAMON and J. BERTRAND (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, March 14th, 1932, p. 366) have made a comprehensive and detailed experimental study of anti-diphtheritic serum and its action; they record various practical inferences that may be drawn therefrom. Their investigations indicated that this serum owing to its antitoxin content could limit and check diphtheritic infection and that a single dose containing a relatively large amount of antitoxin should be administered at the onset of the disease. The size of the initial dose should be determined by considering the age and weight of the patient and especially the apparent severity of the infection; it should contain between 15,000 and 50,000 antitoxin units. If the initial dose proves to be ineffective a second should be administered as speedily as possible. The serum may advantageously be given both subcutaneously and intramuscularly, half the dose being introduced by each route. A high degree of concentration of the serum is not desirable; serums with a high antitoxin content are also frequently concentrated as regards proteins and this retards the neutralization of the toxin by the antitoxin. For treatment serums naturally rich in antitoxin should be employed; concentrated and purified preparations should be reserved for prophylactic use, for which they present certain advantages. A valuable adjuvant measure is disinfection of the nasopharynx and tonsils with an arsenical preparation.

455 Treatment of Disseminated Sclerosis

D. PAULIAN (*Paris Méd.*, February 13th, 1932, p. 145) considers that this disease is an encephalo-myelo-neuritis, one of a group which includes, for example, the encephalomyelitis following infectious fevers or vaccination. The causative virus or neurotropic viruses with close biological resemblances may be held responsible for all the members of the group. Paulian recommends deep radiotherapy and vaccines. The spinal column, or brain, if there are cerebral symptoms, is irradiated with a dose of 300 R on the skin each session. In all the four cases here reported neuro-vaccine was given intravenously in gradually increasing doses of 1, 2, 3 c.cm., either alone or with a 10 per cent. solution of calcium chloride or gluconate, to which may be added a 33 per cent. solution of sodium cacodylate 0·5 to 3 c.cm. Used alone neuro-vaccine injections are followed by a temperature reaction of 100° to 102° F. and the dose can only be repeated after an interval of two or three days, when the temperature is normal again. The author is in the habit of giving 18 to 30 injections of neuro-vaccine which may be repeated if necessary after an interval of one or two months. At the conclusion of the sessions of radiotherapy Paulian recommends daily transmedullary ionization with a 1 per cent. solution of calcium chloride and later iodide ionization. Four cases are reported, three patients were women aged respectively 19, 26 and 31 years and one was a man 26 years old. Good results were obtained in all from this method of treatment.

Anaesthetics

456 Carbon Dioxide in Anaesthesia

D. G. RENTON (*Med. Journ. of Australia*, January 23rd, 1932) points out that while the administration of CO in the course of anaesthesia has many beneficial results there are limitations to its usefulness and in some cases it may do actual harm. Too high a percentage at any stage causes an excessive secretion of saliva and mucus and may lead to post-operative vomiting. In inducing anæsthesia with ethyl chloride or ether, time is saved by adding CO_2. In the case of patients who are very ill or suffering from shock the association of CO_2 with ethylene and oxygen deepens the respiration, raises the blood pressure, and promotes the speed and smoothness of the induction. During the stage of maintenance of anæsthesia the CO_2 is shut off unless there is an indication *for it*—as shown by any depression of the respiration or weakening of the pulse. Deepening of the unconsciousness is obtained by adding a little CO as well as by increasing the anæsthetic when the surgical procedure which called for such deepening has been completed. Withdrawal of the anæsthetic and temporary continuance of the CO quickly renders the anæsthesia lighter. The chief risks of CO administration are found when a bag or other closed system is in use, for the proportion present in the respired gas mixture may rise unduly and prolonged stimulation of the respiratory centre lead to its fatigue. Care should also be exercised in the recovery stage when the respiration should not be unduly stimulated, for this is followed by a washing out of too much CO from the patient and a compensatory period of respiratory depression. At the termination of an endotracheal or pharyngeal anæsthesia this gas is not only useful but necessary, it drives out the accumulated anæsthetic from the body and restores the blood CO_2 to the normal level from which it had necessarily fallen in these two types of anæsthetic induction. In the post-operative stage it is advisable to give short spells of CO_2 inhalation—for five to ten minutes at a time at intervals of two hours in the first twenty four hours, at four hour intervals in the second twenty four hours, at six hour intervals in the third twenty four hours, and so on for as long as may be deemed advisable. In this way collapsed and airless areas in the lungs are opened up and ventilated.

457 Rectal Anaesthesia by Magnesium Salts

P. KOTZOGLU (*Deut. med. Woch.*, April 1st, 1932, p. 535), in view of the difference of opinion as to the absorption of magnesium salts by the bowel, carried out experiments on dogs and found that in a large number of cases general anæsthesia could be effected by the rectal injection of combined solutions of magnesium and lithium chlorides. A clinical trial was then made on twenty-six patients with rectal injections of either magnesium sulphate or chloride. In three cases general anæsthesia was produced by magnesium chloride alone and the operation was performed without the aid of any other anæsthetic. Lithium chloride was tried on only two patients since it produced more severe intestinal irritation than the magnesium salts. No bad after effects were observed in any of the patients treated by magnesium sulphate and chloride or lithium chloride.

458 Avertin Anaesthesia

A. DE WEERDT (*Le Scalpel*, April 9th, 1932, p. 459) agrees with Kirschner that *in order* to obtain a perfect anæsthesia with intravenous avertin a very concentrated solution must be used. This obviates the introduction of a great quantity of foreign matter into the circulation and also produces a more rapid anæsthesia. Kirschner's apparatus is recommended and the technique of its use is described. A 3 per cent. solution of avertin in physiological serum heated to 40° C. should be employed. The dosage must be regulated by the patient's weight (0·03 gram per kg.); this should be given rapidly in 45

seconds. Complete anæsthesia can be obtained in five minutes; it lasts from three to ten minutes and can be supplemented if desired with ether. Avertin anæsthesia can be slightly prolonged by injecting morphine-scopolamine or sedol half an hour before the operation. The awakening is particularly good, malaise, nausea and agitation being absent. Shock is also largely avoided by this method, and no ill effects have been noted. The respiration is slightly accelerated and superficial, and cyanosis usually occurs. Should respiratory paralysis ensue, the appropriate remedial measures must be employed. Avertin anæsthesia is contraindicated in serious hepatic, renal, and intestinal diseases, advanced tuberculosis, cachexia, and in grave anæmias.

459 H. HILDE (*Med. Welt*, March 26th, 1932, p. 455) points out that the greatest value of avertin is in anæsthetics lies in the fact that by rectal introduction the psychological effect can be cut out. Again, avertin is easily administered, and 86 per cent. is quickly absorbed by the healthy rectum in 25 minutes; one disadvantage is that it is impossible to stop absorption once it has commenced. The anæsthetic has been found to have a selective paralysing action on the respiratory and circulatory centres. It is especially indicated in operations for exophthalmic goitre, since in these patients psychological shock can be completely eliminated. It also has a place in operations for hare-lip and cleft palate in children, plastic operations in adults, thoracoplasty, and rib resection. Emergency operations may be successfully carried out under avertin anæsthesia, and Hilde uses it to induce euthanasia in cases of carcinoma with metastases in the vertebral column and pelvis. Although an ideal anæsthetic in operations for abdominal conditions which are complicated by heart or lung disease, it is not well tolerated by anæmic or cachectic patients, or those in whom there is an acute septic inflammatory process present, and is contraindicated in such cases. No special pre-operative treatment is needed; enemata are forbidden since they decrease the absorptive power of the rectum. Morphine is not injected because it has, together with avertin, a cumulative action which paralyses the respiratory centre. Patients with exophthalmic goitre are given pseudo-enemata three to four days before operation; the same procedure is carried out in children to accustom them to retain the drug on the day of operation. Overdosage and bad technique account for most of the disadvantages and dangers. The dose for each patient has to be calculated; the amount of avertin in a 3 per cent. solution should not exceed 8 grams in a woman and 10 grams in a man. It is dissolved in amyl hydrate (1 gram to 1 c.cm.) and distilled water at body temperature is added. The solution should be administered slowly (20 to 30 minutes being taken) so that too rapid absorption may not occur.

Obstetrics and Gynaecology

460 High Caesarean Section

V. Cocq (*Bruxelles Medical*, March 20th, 1932, p. 579) records his impressions of the value of high Caesarean section and enumerates the indications for this operation based on a critical survey of 300 personal cases as compared with fifty in which the low Caesarean procedure was employed. He compares the two operations from the point of view of simplicity of technique, the nature and frequency of accidents which may occur, the maternal mortality, the late sequels which may be imputed to the operation, and the foetal mortality. Although the low operation is indicated in certain forms of dystocia, Cocq considers it would be a mistake to look upon the high procedure as superseded. In the treatment of contracted pelvis, disappointment is likely if a segmental Cæsarean operation is tried instead of podalic version. In clean cases, high Cæsarean section is considered the technique is simple, accidents are rare, uterine rupture is not to be feared, and there are fewer risks of tears since the wound is larger and further removed from the dangerous region. The author finds that the foetal mortality is exceptional, adhesions are [illegible] operation are less likely to interfere with a repeated operation, [illegible] in a succeeding pregnancy, possibly [illegible] in the low operation, but Cocq did not [illegible] as frequent as some authors state, and [illegible] section should not be used as a prophylactic [illegible] should always be given the benefit of trial [illegible].

461 Primary Abdominal Pregnancy

R. HASSELBALCH (*Zentralbl. f. Gynäk.*, February 13th, 1932, p. 404), who records a personal case, calls attention to the rarity of primary abdominal pregnancy by the fact that he could find only thirty-three cases recorded. A factor in the abdominal implantation of the ovum is the migration of the fertilized ovum from the left ovary to the right side of the pelvis, where there is no Fallopian tube to catch the ovum. The rarity of primary abdominal pregnancy prevents a differential diagnosis being made with certainty. The only possible treatment consists in operation as quickly as possible. Hasselbalch's patient was a multipara aged 24, who had had an abortion two and a half years previously and had undergone right salpingo-oophorectomy in the previous year. She developed violent abdominal pain after coitus, being in the fourth month of pregnancy. Laparotomy was performed on the following day, and a living foetus (which died within a few minutes of removal) was found between the intestinal coils below the liver. Death ensued two days after the operation.

462 Ovarian and Uterine Carcinoma

SUSAN R. OLCOTT (*Surg., Gynecol. & Obstet.*, March, 1932, p. 490) has endeavoured to ascertain the frequency with which ovarian papillary cystadenocarcinoma is associated with carcinoma of the fundus uteri. A series of cases operated upon at the Mayo Clinic during the seventeen years in which carcinoma appeared in both these structures is recorded, and the possible modes of extension from one organ to the other briefly reviewed. In 520 cases of uterine adenocarcinoma ovarian involvement occurred in 11·9 per cent.; in 616 cases of ovarian papillary cystadenocarcinoma there was associated uterine carcinoma in 8·6 per cent. From the cases [illegible] in which the disease was not far advanced it [illegible] evident that the blood and lymphatics were not [illegible] of metastasis. The author thinks that the Fallopian tube should be considered as one means through which implantation takes place. Because of the similarity of adenocarcinomatous cell in the embryologically [illegible] tissues it is often difficult to determine which [illegible] is primary and which a secondary, or whether they may not originally have been two independent growths. In ovarian carcinoma the possibility of [illegible] the uterine endometrium even when [illegible] evidence of tumour extension [illegible] in mind, and hysterectomy [illegible] must be seriously considered.

463 Referred Pain of Ureteral Origin

The efficacy of [illegible] (*Lettres Internationales de Médecine et de Chirurgie*, February, 1932, p. 259) claims that [illegible] to the mild [illegible] the nerve supply of the [illegible] conditions of the [illegible] assume special [illegible] the unfortunate [illegible] curious [illegible] ureter [illegible] nerves over the [illegible] Diabetes of the [illegible] pain. Professor [illegible] therapeutic [illegible] by [illegible] obtained when [illegible]

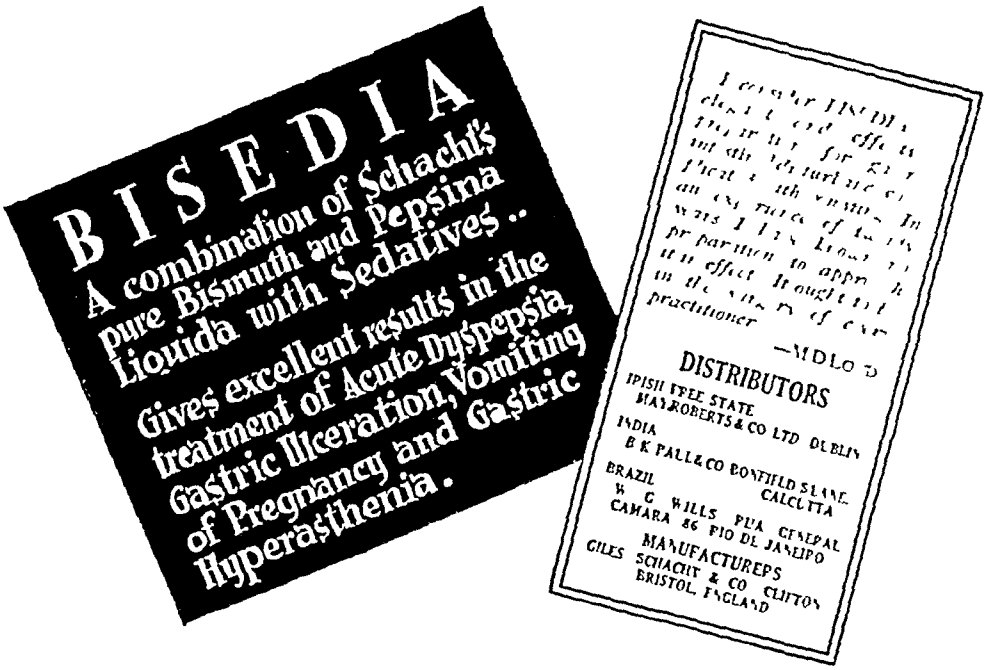
were cured It is well recognized that lesions of the urinary tract may be confused with those of the pelvic organs gall bladder and appendix The incidence of this referred pain of ureteral origin was 10 per cent in 1 161 recent cases Comparatively few of these patients presented obvious urinary symptoms as their chief complaint Very few even with vesical irritability showed either pyuria or recent inflammation of the bladder or urethra The clue to their causative lesions was the correct interpretation of the pain A series of typical cases is recorded with note of the areas to which pain was referred in such condition as afterwards proved to be renal ptosis hydro, or stricture of the ureter, and tumours of the ureteral meatus Urograms made by the pyelo opaque method were employed to demonstrate the local condition

Pathology

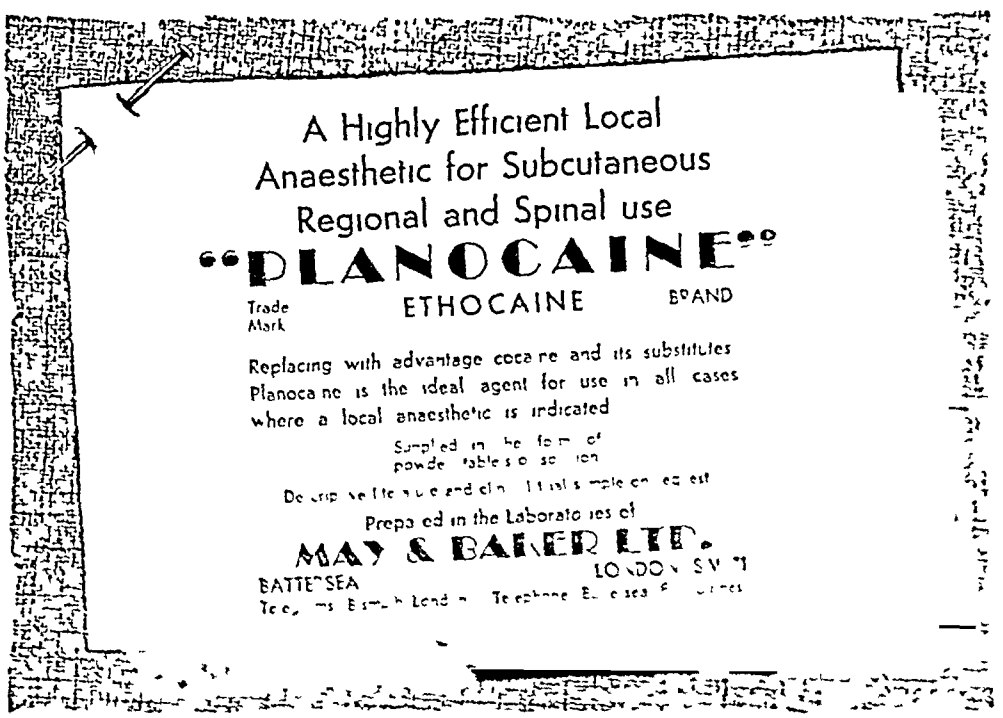
464 Occurrence of Avian Tubercle Bacilli in Milk

K J Worthington and H Dimmock (*Vet J Zeitschr der Haustiere* March 7th 1932 p 71) draw attention to the frequency in cattle of infections with the avian type of tubercle bacillus Examining mixed samples of milk by guinea pig inoculation and by cultural methods they have succeeded in a number of instances in isolating acid fast bacilli in culture from milks that gave rise to no detectable lesions in guinea pigs Investigation of these strains by the usual cultural and animal inoculation methods has shown that they are undoubtedly of avian type It was observed that positive results were obtained only with milk comin, from milk farms having about two score animals in the herd of milk from large farms avian tubercle bacilli were never isolated in routine cultures The individual animals in six small farms were examined both the milk and the lung mucus being tested by cultural and animal inoculation methods From seven cows on four different farms avian tubercle bacilli were recovered in culture Large farms were then investigated and by the examination of individual animals the authors succeeded in obtaining six cultures of avian bacilli from milk and three from lung mucus So far as could be ascertained the infected animals were quite healthy Comparison of the avian strains of cattle origin with avian strains isolated from fowls showed that the former were as highly pathogenic for rabbits as the latter The situation of the lesions in infected cattle was not established but the authors recall Plum's findings of avian tubercle bacilli in the uterus of pregnant cows

465 The Nature of the Agent Transmitting Fowl Leukaemia



J Furth (*Journ Exper Med* March 1932 p 465) cites evidence to show that the concentration of the transmitting agent of fowl leukaemia is approximately the same in cell free plasma as in suspensions of blood cells The smallest amount of plasma producing the disease was 0 000001 c cm and of cell suspension 0 00001 c cm This observation seems sufficient to exclude the possibility that transfer by plasma is due to a small number of cells remaining in it for leukaemic blood diluted 1 in 1 000 000 still contains 100 to 1 000 leucocytes per c cm, yet is unable to produce leukaemia moreover, observation failed to reveal the presence of cells in the original undiluted plasma yet the same plasma in high dilution proved infective The incubation period of the disease was prolonged by decreasing the amount of plasma injected diminution of the number of leukaemic cells injected had, however much less effect in lengthening the incubation period The author concludes that the filterable agent in plasma presumably brings about a neoplastic formation of some of the elements in the bone marrow of the host whereas leukaemic cells are themselves capable of multiplication in susceptible hosts Transfer of the disease by cells is essentially a tumour graft, whereas transfer by cell free plasma acts only by inducing a neoplastic process in the tissues In a second paper (ibid p 479) the author states that the virus will pass through all siliceous filters and is probably more or less similar in size to the bacteriophage In a third paper (ibid p 495) experiments are recorded on the resistance of the transmitting agent It was found that the filterable virus in blood was able to withstand drying for at least fifty four days It was not inactivated by freezing in liquid air At 37 5° C it lost its activity within fourteen days but retained part of its activity for this time if it was kept at 4° C



466 Action of the Heavy Metals in Anaemia

K W Schultze (*Klin Woch* March 19th 1932, p 497) established anaemia in a number of young rats by feeding them with pure cow's milk a practically mineral free diet and observed the results of adding to the milk small amounts of nickel cobalt copper, and iron on the production of red blood cells and haemoglobin Daily doses of 0 5 mg nickel had no effect on the anaemia but doses of 2 mg caused a rapid increase of the erythrocytes and a slow rise in the haemoglobin with older animals nickel exerted no influence on the blood picture Cobalt induced a marked fall in the body weight and the animals usually died about the tenth day in the older animals there was an increase in the number of red cells and in the haemoglobin with a fall in the body weight Copper had a considerable influence in producing erythrocytes but only a slight effect on the haemoglobin formation in older animals a dose of 2 mg reacted only in one case Administration of 1 mg of iron to the older animals was without effect But with young rats a like dose rapidly relieved the anaemia It is explained that in grown rats there is a sufficient store of iron in young animals this is not the case and they can easily assimilate an extra dose of it A pure milk diet soon causes anaemia in young animals whereas older animals are longer resistant and can be restored to the normal by doses of cobalt nickel and copper without iron the prophylactic administration of these heavy metals can hinder the production of anaemia A stimulus to the haemopoietic system by these heavy metals reacts on the anaemia of grown animals by the equal new formation of haemoglobin and red cells —a constant colour index with younger animals under a similar stimulus red cells can be formed but owing to iron deficiency the haemoglobin synthesis fails and the colour index falls In erythropoiesis the production of red cells and the formation of haemoglobin are independent whereas iron influences both in the same manner, the nearly related metals cobalt nickel and copper exert a formative stimulus and with deficiency of iron do not effect the synthesis of haemoglobin The catalytic effect of various metals depends on a formative stimulus on the red bone marrow, the results of liver therapy in anaemia are probably in great part due to the action of copper

467 Syphilis and Cancer

The possibility that syphilis may be a factor in the genesis of adenocarcinoma with hepatic cirrhosis was first suggested by Menetrier in 1917 A Tournaire and P Renault (*Bull Soc Franç de Derm et de Syph* February 1932 p 269) report and fully describe a case, which apparently confirms this theory of the carcinogenic action of syphilis In this patient the disease, contracted thirty nine years previously had been only moderately treated and showed a recrudescence of activity twenty two years later with a positive Wassermann reaction Alcoholism appeared to intensify markedly the action of the syphilitic infection on the liver These two processes caused a series of attacks of hepatic congestion, and the liver became permanently hypertrophied some thirty eight years after the onset of syphilis Laparotomy was then performed, and a typical trabecular epithelioma evidently originating from the hypertrophic cirrhosis was found The patient died about three months later The authors believe that a pre existent syphilitic inflammation although often noted in various other organs has rarely been considered in the case of hepatic epithelioma, particularly of the adenocarcinomatous type

BRITISH SPAS
. *are* BEST

NO country in the world offers such a variety of natural mineral waters and spa treatments as are available in Great Britain At British Spas the staffs are educated and properly trained and, in most cases, medically trained and certificated Equipment and administration are thoroughly up-to-date and scientific

British Spas are also remarkably fortunate as regards situation, scenic beauty and pure air These factors, combined with the social amenities of a home town, aid the cure considerably

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY

President THE MOST HON THE MARQUESS OF LOTHIAN C.M.G., A.D.C.

Medical Superintendent DAVID F. LAMBERT, M.A., M.D.

This registered Hospital is situated in large grounds of park and pleasure grounds. Voluntary patients who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes are received for treatment at the hospital. Clinical, biochemical, bacteriological and pathological examinations. Private cases with or without trained nurses can be treated in the Hospital or in one of the numerous villas in the grounds of the hospital. Various forms of occupation can be provided.

WANTAGE HOUSE.

This is a fine modern Hospital standing in its own grounds with a separate entrance to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish, Russian and Electric Baths, Hydrotherapeutic Bath, Vichy Douche, Scotch Douche, Needle Bath, Shower Douche, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room and a Diathermic Apparatus, and a Department for Diathermy and High Frequency treatment. Blood examinations, Laboratory Experimental, Bacteriological and Pathological research.

MOULTON PARK

The Main Hospital and Moulton Park are several branch establishments and villas within the park and farm of 600 acres. Milk, eggs, fruit and vegetables are supplied from the Hospital farm, gardens and orchards of Moulton Park. Occupation therapy is a feature of the treatment, and patients are given every facility for occupying themselves in the farm, garden and fruit grounds.

BRYN-Y-NEUADD HALL

The Hospital for Nervous Diseases, Bryn-y-Neuadd Hall, is beautifully situated in a Park of 330 acres, 1,000 feet above sea level. The Hall is the property of the North Wales Hospital, and forms the Tuberculosis Branch of that institution. Patients may visit this branch for a short period. There is a golf course in the Park. The Hospital has its own private bathing house on the sea shore. There is fishing in the Park.

At the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts, a 9-hole golf course, croquet lawns, putting greens, bowling greens, fives courts, and a gymnasium. There are large gardens and facilities are provided for handicrafts, such as carpentry.

Further particulars may be obtained by applying to the Medical Superintendent at the Hospital (Telephone No. 2356 Bangor). Patients will be received on any day of the week by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE

Three miles from Warrington on Main Road to Liverpool

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supporting. Its own farm and gardens in which patients are encouraged to occupy themselves. Every facility for indoor and out door recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

THE COPPICE, NOTTINGHAM
HOSPITAL FOR MENTAL DISEASES

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from its singularly healthy position and comfortable every facility for the relief and cure of those mentally and Temporary Patients received.

TREATMENT OF RHEUMATISM

For many years Pistany has been appreciated by the Medical Profession for its great work in the cure of Rheumatism.

The properties of Pistany's hot volcanic soft mud are quite peculiar Its power of stimulating and increasing the absorption of pathological products is still unrivalled

The treatment may be continued by the patient after returning from the Spa under his own doctor's supervision by means of the Mud Packs which are in use in many rheumatism clinics in this country

Write for free booklet, and at the Coupon rate for value for treatment at Pistany Spring Establishments

NOTE.—A special grant will be available in respect of Surgical qualifications and service.

Applications with statement of qualifications and experience accompanied by copies of three recent testimonials to be lodged with the undersigned not later than Thursday, May 26th.

County Buildings, Inverness. J. W. McKILLOP
May 9th 1932 County Clerk

MEDICAL CORRESPONDENCE COLLEGE

19 WELBECK ST. LONDON W.1 Tel. Welbeck 8391

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS

Special Preparations for all Surgical Qualifications

F.R.C.S. ENGLAND (Primary & Final.) M.C. CANTAB

F.R.C.S. EDINBURGH M.S. LONDON

And all other Surgical Degrees and Diplomas.

- The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.
- Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our courses.
- The Surgical Tutors of the College all hold either the M.S. London or F.R.C.S. England and are highly experienced teachers.
- The Postal Courses are thoroughly clear, concise and up to date, and the text questions are carefully selected from those set at previous Examinations so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time and much unnecessary reading is saved.

COUNTY COUNCIL OF DURHAM

ASSISTANT WELFARE MEDICAL OFFICER

The County Health Committee invite application for the appointment of an Assistant Welfare Medical Officer (woman) at a commencing salary of £500 per annum (subject to such temporary reduction as the County Council may order) rising by annual increments of £25 to £600 per annum. Travelling expenses will be paid by the County Council according to scale.

The appointment will be held subject to three months' notice on either side and to the following conditions:

(1) The officer appointed must be a registered Medical Practitioner between the ages of 25 and 45 years, must devote the whole of her time to the duties of the office and must not engage in private practice.
(2) She should either have held a previous appointment as Medical Officer of an Ante Natal clinic, with the approval of the Minister of Health or have had at least three years' experience in the practice of her profession and special experience of practical Midwifery and Ante Natal work. The holding of a Diploma in Public Health and practical experience in Bacteriological Laboratory work will be deemed additional qualifications for the post.
(3) She will be subject to the directions of the County Medical Officer.
(4) She will be required to reside in Durham City or such other place as required by the Council.
(5) She must be prepared if called upon to act as Locum Tenens to other members of the Medical Staff of the County Medical Officer.
(6) The appointment will terminate on marriage.
(7) The candidate appointed will be required to pass the County Council's medical examination, and will be subject to the provisions of the Local Government and Other Officers' Superannuation Act 1922.

Applications endorsed "Assistant Welfare Medical Officer" with copies of not more than three recent testimonials must be received by the County Medical Officer, Shire Hall, Durham not later than the 28th instant.

Shire Hall, Durham. HAROLD JEVONS
May 9th 1932 Clerk of the County Council.

RICHARD MURRAY HOSPITAL BLACKHILL CO DURHAM

SURREY COUNTY COUNCIL

ASSISTANT MEDICAL OFFICER

Applications are invited for the appointment of an Assistant Medical Officer. Candidates must be qualified in Public Health and must have had experience in the work of a Local Authority. The appointment will be subject to the provisions of the Local Government Superannuation Act, 1922, and to the Rules of the Council applicable to officers in the Medical Service. Salary £450 per annum, rising by annual increments of £25 to £500 per annum, subject to the passing of a medical examination. Applications, stating age, experience and qualifications, accompanied by copies of four testimonials, not earlier than May 24th, to be addressed to the undersigned.

HUBERT MILLARD
County Hall, Kingston-on-Thames.
May 10th, 1932.

LONDON COUNTY COUNCIL

Applications are invited for the appointment of a Female Assistant Medical Officer in the Public Health Department at a salary at the rate of £450 per annum, rising by annual increments of £15 to £500 per annum. The appointment will be subject to the provisions of the Local Government Superannuation Act, 1922. Applications, on forms obtainable from the Education Officer, Victoria Embankment, W.C.2, must be returned to the Education Officer not later than May 21st.

By Order of the Council,
JAMES G. LEGGE,
Clerk of the London County Council.
May 3rd, 1932.

LONDON COUNTY COUNCIL

Applications are invited for appointment as Tuberculosis Medical Officer (part-time) in District No. IX (Deptford). Applications until December 31st, 1932, in the direction since.

The candidate appointed will be required to reside in or near the district and to carry out the duties prescribed by the Public Health (London) Act, 1891, and Orders of the London County Council made thereunder. The candidate appointed will be required to preside at his own expense at an approved dwelling during at least three hours each week.

Remuneration at the rate of £210 a year, subject to deduction on account of superannuation.

Forms of application, with further particulars of the duties, may be obtained by candidates personally from the Medical Officer of Health (Staff Division), County Hall, Westminster Bridge, S.E.1, returnable by May 20th.

Canvassing disqualifies.

EVELINA HOSPITAL FOR SICK CHILDREN
Southwark, S.E.1

Applications are invited for the post of HOUSE PHYSICIAN (male) for six months from June 13th (first two months in Casualty and Out-patient Departments). Salary at the rate of £150 per annum, with board and residence.

Applications, stating age, experience and qualifications, accompanied by copies of four testimonials (of whom at least three must be recent), to be sent to the undersigned not later than May 24th, from whom further particulars can be obtained.

By Order of the Committee of Management,
W. D. SPINNEY,
Secretary Superintendent.
May 10th, 1932.

KING GEORGE HOSPITAL
Ilford (London)

Applications are invited for the appointment of HOUSE SURGEON (male). Salary £100 per annum with board, residence and laundry. Term six months with eligibility for a further period. Applications should be sent immediately to the Secretary.

CITY AND COUNTY OF KINGSTON-UPON-HULL

HULL MUNICIPAL MATERNITY HOME AND INFANTS HOSPITAL

JUNIOR RESIDENT MEDICAL OFFICER
(Male)

The Committee invite applications from unmarried or widowed Women Medical Practitioners for the appointment of Junior Resident Medical Officer at the Maternity Home and Infants Hospital, Hessle Road, Hull.

Salary at the rate of £100 per annum, with board, lodging, and residence at the Maternity Home.

The appointment will be for six months, with a view to a further period of office.

The successful candidate will be required to undertake the duties of Anæsthetist.

Medical officers appointed will be given opportunities of obtaining post-graduate experience in obstetrical and gynæcological practice, and in the treatment of venereal diseases.

The Council require the whole of the time of the officers appointed to be devoted to the duties of the appointment which will also include attendance at occasional evening meetings of the Committee.

Applications, endorsed "Junior Resident Medical Officer," stating age, qualifications, and experience, together with copies of three recent testimonials, must be delivered at the Maternity Home, Hessle Road, Hull, not later than Monday, May 16th, 1932.

Canvassing will disqualify.

ARTHUR E. HOWARD,
Medical Officer of Health.
Health Department, Guildhall, Hull.
May 4th, 1932.

CITY AND COUNTY OF BRISTOL

ASSISTANT MEDICAL OFFICER OF HEALTH

The Council desire applications for a whole-time appointment as Assistant Medical Officer of Health. Age not exceeding 40 years. Salary £500 per annum, rising by annual increments of £25 to £600 per annum (a temporary reduction).

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Duties will commence on a date to be arranged.

Applications, in the handwriting of the candidate, delivered to the Council's Solicitor, Council House, Bristol, not later than noon on Saturday, May 21st, 1932, must be accompanied by copies of not more than three recent testimonials, and should be addressed to the undersigned.

Canvassing will disqualify.

JOSIAH CLEEN,
Town Clerk.
May 4th, 1932.

CHESTERFIELD AND NORTH DERBYSHIRE ROYAL HOSPITAL
(220 Surgical and Medical Beds)

HOUSE SURGEON

Applications are invited from fully qualified men for the above post. There are five Resident Visitors at the rate of £150 per annum with board, apartment and laundry.

Applications, stating age, together with copies of three recent testimonials, should be sent to the undersigned.

G. SUNNUCK,
April 18th, 1932. Supt. & Secretary.

CONNAUGHT HOSPITAL
Walthamstow, E.17
(100 Beds with Three Resident Medical Officers)

RESIDENT CASUALTY OFFICER (male) required. Salary £100 per annum. Appointment for six months from June 1st with board, residence and laundry. Applications, stating age, nationality, qualifications and experience, accompanied by copies of not more than three recent testimonials, should be received not later than Monday, May 16th, by the Secretary.

HAROLD S. PHILLIPS.

THE GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION
GLOUCESTER

There is a vacancy for an ASSISTANT SURGEON on the Acting Medical Staff of this Institution.

Candidates should send in their applications, with testimonials and references to the diplomas and testimonials, and letters to the undersigned on or before the day, June 14th.

F. J. SIMMONS, Secretary.

ESSEX COUNTY COUNCIL

PUBLIC ASSISTANCE DEPARTMENT

MEDICAL OFFICER

The Public Assistance Committee invite applications for the appointment of Medical Officer at the Mild and Public Assistance Institution and Children's Home, The Gables, Maldon.

The remuneration for the Institutional appointment will be at the rate of £120 per annum, plus £10 per annum for the Children's Home, and the emoluments etc. will be supplied by the Committee.

The successful applicant will be required to pass a medical examination.

It is probable that superannuation contributions at the rate of 5 per cent. will be deducted from the salaries in accordance with the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Applications for the above position to be made on form obtainable from the Public Assistance Officer, Industrial Buildings, Duke Street, Chelmsford, must be returned to him by May 21st.

By Order,
Shire Hall, JOHN H. GOOLD,
Chelmsford. Clerk of the County Council.
May 5th, 1932.

ESSEX COUNTY COUNCIL

PUBLIC ASSISTANCE DEPARTMENT

CONSULTANT OPHTHALMOLOGIST

The Public Assistance Committee invite applications for the appointment of Consultant Ophthalmologist who will be required to attend an average of one half-day session per month, mainly at the OLDCHURCH HOSPITAL, ROMFORD, or elsewhere in the County on request. The appointment is for one year in the first instance.

The remuneration will be at the rate of fifty guineas per annum, plus travelling expenses in accordance with the County scale.

Applications for the above position to be made on forms obtainable from the Public Assistance Officer, Industrial Buildings, Chelmsford, must be returned not later than May 21st to the County Medical Officer, County Hall, Chelmsford, in an envelope endorsed "Consultant Ophthalmologist."

By Order,
Shire Hall, JOHN H. GOOLD,
Chelmsford. Clerk of the County Council.
May 3rd, 1932.

CITY OF LIVERPOOL

RESIDENT ASSISTANT MEDICAL OFFICER

Applications are invited for the above appointment at the SMITHDOWN ROAD HOSPITAL (1,200 Beds), Liverpool, for a period of one year at a salary of £200 per annum (subject to the usual deductions authorised by the Council), together with the usual residential allowances. Canvassing will be deemed a disqualification.

Applications to be made upon forms obtainable from the Medical Officer of Health, Municipal Annexe, to be endorsed "Resident Assistant Medical Officer," and returned to the undersigned so as to be received not later than Tuesday, May 24th.

Municipal Buildings, Liverpool. WALTER MOON, *Town Clerk.*
May 9th, 1932.

MANCHESTER AND DISTRICT RADIUM INSTITUTE

The following appointments are contemplated to the staff of the Institute. They offer a unique opportunity of acquiring experience in Radium Therapy (and Deep X-ray). Both appointments are for six months in first instance but with view to reappointment for another month.

1. ASSISTANT MEDICAL OFFICER (male) at £500 per annum. Candidates must possess either the D.M.R.E. or F.R.C.S. and have had a good general Surgical experience but not necessarily previous experience in Radium Therapy.
2. CLINICAL ASSISTANT at £250 per annum. Candidate must have an excellent academic record and preferably some subsequent experience.

Application, with copies of testimonials to be sent to the Honorary Secretary not later than June 3rd.

KING EDWARD HOSPITAL FUND
(London)

Applications are invited for the appointment of HOUSE SURGEON (male). Salary £100 per annum with board, residence etc. Term six months with eligibility for a further period. Applications should be sent immediately to the Secretary.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880)

12, Stratford Place,
Oxford Street, W.1.

Telephone Mayfair {1782 / 1783

The Bureau has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending readers to consult Mr. A. V. STORIA, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners desirous to dispose of Practices, or desirous to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUM TENENS

Assistants and Locum Tenens can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY

The British Medical Bureau has its own staff of qualified Accountants wholly engaged on medical work—Valuation of Practices for purchasers, Income Tax, Auditing Accounts, etc.

Triumphant Motherhood

First Prize winner of the News Chronicle Mother and Child Beauty Competition

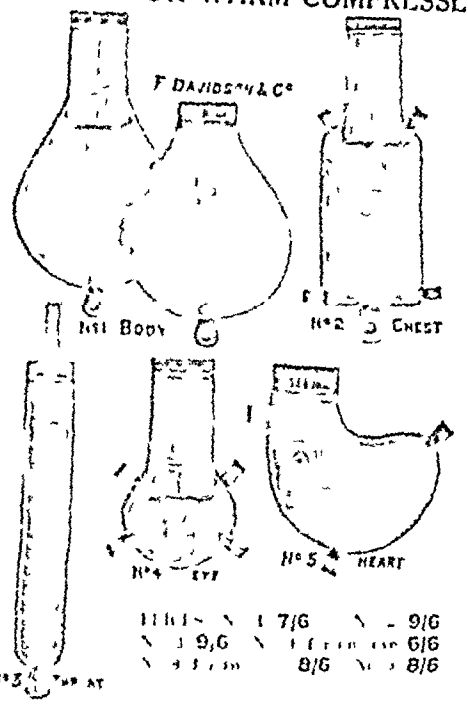
IN the past the choice of an artificial food when for any reason an infant could not be breast fed imposed a heavy responsibility upon the physician In recent years the increasing range of Cow & Gate Milk Foods designed to meet any aspect of infant feeding no matter how difficult has done much to lighten this burden

This picture of a happy mother and a healthy intelligent child is typical of the results which the profession are achieving all over the world with this remarkable substitute for natural milk

Clinical samples and literature of the Cow & Gate Products will gladly be sent on request

Cow & Gate Milk Food

"The Best Milk for Baby when Natural Feeding Fails"



COW & GATE LTD GUILDFORD SURREY

NEW APPLIANCES RECOMMENDED AND SOLELY DISTRIBUTED BY

F. DAVIDSON & CO.

143-149, GREAT PORTLAND STREET, LONDON, W1 (Estd 1890)

BRAUN'S (of Melsungen) COMBINED ICE BAGS OR WATER BOTTLES FOR COLD OR WARM COMPRESSES

Nos 1 and 2 7/6 No 3 9/6
No 4 9/6 No 5 Ear or Throat 6/6
No 6 Spine 8/6 No 7 8/6

NO LOSS OF STOPPER NO LEAKAGE

No 1 CAN BE USED AS AN AIR CUSHION

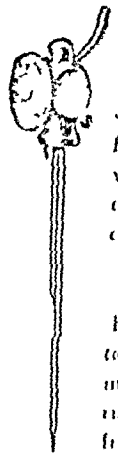
In the neck of the bag is a flexible metal plate which when the neck is pinched together and rolled tightly to the end of the plate (as at No 1) forms a perfect and impervious water tight joint. No thumb screw needed

"FLAT FOOT"

or a "Falling of the Arch"

In the case of many troublesome ailment

THE "PNEUMETTE" (Patented)



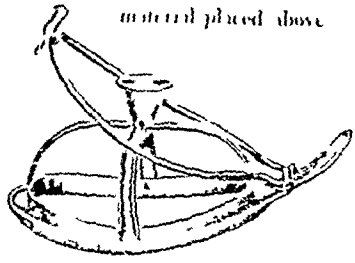
THE ONLY FOOT ARCH SUPPORT WITH AN AIR CUSHION

SUPPLIED ON FOOT FROBERS with an Attach The Medical Adviser of Health says "It is an eminent London Physician

I have prescribed Pneumettes for several of my patients with remarkable results in every case — M.D.

I have been an arch sufferer for very many years. My walk was painful to watch, I was gradually but surely failing. I suffered at times from cramp in my ankle and leg and also from almost constantly false sensation. I tried every possible form of appliance and support made. They only meant exchanging pain from one part of the instep for another and at times a worse one. Now at the age of 71 I am going in a new pair of legs and the troubles of the past seem like a bad dream. Pneumettes have given me a new lease of life. — F. DAVIDSON

BRAUN'S ETHER DROPPER AND MASK

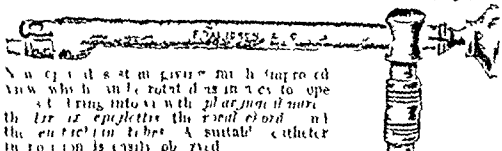


ADVANTAGES

The DROPPER is inserted through the stopper of the bottle. Perfect adjustment for the flow of the ether by means of the valve "open" or "closed" for slow dropping or continuous flow. No decomposition and saving of ether.

Price 12/6

The MASK eliminates loss by evaporation or otherwise. The ether flowing into the funnel (removable) is allowed to run over the flatly fluted rib of the frame and is sucked up the soft material placed above.



PRICE 12/6

A perfectly even distribution is obtained. The employment of the mask in conjunction with the dropper ensures a great saving of ether.

One of our leading Anæsthetists reports as follows: I am obliged that you have given me the opportunity of trying out the dropper and mask. I used them on four jobs with pleasure and two in private. The dropper is quite good and does what it professed to do, and the mask is also satisfactory.

LARYNGO-PHARYNGOSCOPE (Parel's foreign)

New operating system giving much improved view which can be rotated as desired. Fitting into with pharyngeal mirror, the laryngeal epiglottis, the vocal cords and the entrance tubes. A suitable catheter in position is easily observed.

With Handle and Cords, £6 0 0 In Walnut Box £6 10 0

Davon Dry Battery for above 0 7 6

With Davon Battery and Rheostat in Walnut Box 7 10 6

With battery in handle (not the Davon) 6 0 0

Or complete with Electric Auriscope for diagnosis, operating, cauterising and massage in Oak Case 9 0 0

THE DAVON (Reg) DRY BATTERY, 4 volt, Price 7/6, is the most reliable long life Battery on the market. It is a 12 cell Battery, and can be used for light cautery as well as light. Our Guarantee is behind it. It has been used by many doctors for two years and we have numerous testimonials. Do not be misled. There is no Battery "just as good"

Advances in Endocrine Therapy

Parke Davis & Company announce the following two important additions to their range of endocrine products

ESCHATIN

An extract of suprarenal cortex manufactured exclusively by Parke Davis & Co with the direct co-operation of Drs Swingle and Pfiffner the originators

The preparation is intended for intravenous or subcutaneous injection in the treatment of Addison's disease

Each c.c. is supplied in rubber capped vials of 10 c.c.

ANTUITRIN "S"

Antuitrin S is a solution of the sex stimulating hormones elaborated by the anterior lobe of the pituitary gland The solution possesses both follicle stimulating and luteinising properties

Antuitrin S is physiologically assayed, and the potency expressed in rat units based on its ability to cause the formation of corpora lutea in immature female rats

Antuitrin S is indicated for the treatment of menorrhagia metrorrhagia climacteric haemorrhage and habitual abortion as well as for functional amenorrhoea delayed puberty etc

Antuitrin S is supplied in vials of 5 c.c. and 10 c.c.

CANCER: CIVILIZATION: DEGENERATION

The Nature, Causes and Prevention of Cancer, especially in its Relation to Civilization and Degeneration.

By JOHN COPE

Extract from Author's Note "The writer has had more than a generation of experience in the investigation of human cancer and has closely studied the subject in all its aspects On taking an all round view he sees convincing evidence that the secret of the cause of human cancer is far likely to be found among mice and fowls in the close and stuffy atmosphere of the laboratory than it is by the study of human beings, not only in their biological and pathological aspects but in their wider relations as members of societies nations or races"

ORTHOPAEDIC SURGERY

By WALTER MERCER, MB., ChB FRCS(Edin) FRS(Edin)

With a Foreword by Professor JOHN FRASER

Mr Mercer's comprehensive new text book is based upon the lectures and clinics which he has given for Fellowship students It fully covers the requirements of the FRCS examination and will also be found a most valuable work of reference I believe says Professor Fraser that Mr Mercer has contributed a most readable and practical treatise I know how great has been his enthusiasm I have some knowledge of the care which he has bestowed upon every page and if these are the hall marks of a successful publication the volume assuredly deserves success

PAR EXCELLENCE

When children lack Vitamin "B"

IMPORTANT—An article dealing with further research in Vitamin Pathology will be published by us to Members of the Profession within the next few days

Partial deficiency of vitamin B may be suspected in children when strength growth and resistance to disease are impaired and there is evidence of gastro intestinal disturbance The encouraging results attending the use of Bemax in such cases suggests that this rich source of natural vitamins should be a regular part of the daily diet of every growing child

Bemax is a preparation of the detoxicated embryo of cereals, very rich in natural vitamin B, and containing vitamins A and E It is a pleasant food, welcomed by children for its flavour Taken regularly it stimulates healthy growth promotes digestion, checks constipation and tones the system to vigorous health and resistance to disease In convalescence its tonic properties are invaluable

BEMAX

MANCHESTER

TAB. ARTHRITONE

H, H & Co.

It is Significant that so many of the Medical Profession when prescribing "Liquor Carbonis Detergens" add the word Wright's

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar") the method of manufacture is unique Imitations will be found to be produced by simple digestion usually accompanied by some primitive perfunctory and inadequate stirring whereas in the case of the genuine product the intimate contact required for the complete extraction of all the soluble antiseptic constituents is attained by a series of complicated processes involving the use of highly specialized machinery

On receipt of your professional card a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap
Wright's Coal Tar Ointment
Wright's Lysol
Wright's Liquor Carbonis Detergens

ALOCOL

Colloidal Hydroxide of Aluminium

For Chronic Irritations of the Gastric Mucosa

WHEN alkaline therapy is indicated Alocol is the preferred form of treatment Its advantages over the usual oxides and alkalis are manifest Whilst the preparations in common use give momentary relief to painful symptoms they aggravate the morbid condition Consequently such remedies are contraindicated especially in stubborn chronic cases

The action of Alocol is superior in every way because it does not merely confine itself to combating the symptoms of the trouble but attacks the origin itself

Alocol fixes the acid not by neutralization but by adsorption It relieves pain is slightly astringent and limits the acid secretions Alocol is always well borne no harmful secondary action follows its administration and its therapeutic effect is not diminished with prolonged use

Complete clinical history of Alocol with convincing clinical reports and supply for trial sent free to physicians on request

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl salicylic acid possesses a notable disadvantage Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach Consequently the value of this medicament in the wide field in which it is indicated is very seriously reduced

Alasil completely overcomes this objection By combining calcium acetyl salicylate with Alocol unfavourable secondary action upon the stomach is prevented This beneficial influence is undoubtedly due to the presence of Alocol (Colloidol Hydroxide of Aluminium) which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. Alasil is therefore a triumph over acetyl salicylic acid It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time Analgesic Antipyretic and Sedative Alasil is indicated in all cases where acetyl salicylic acid has been used heretofore

A supply for clinical trial with full descriptive literature sent free on request

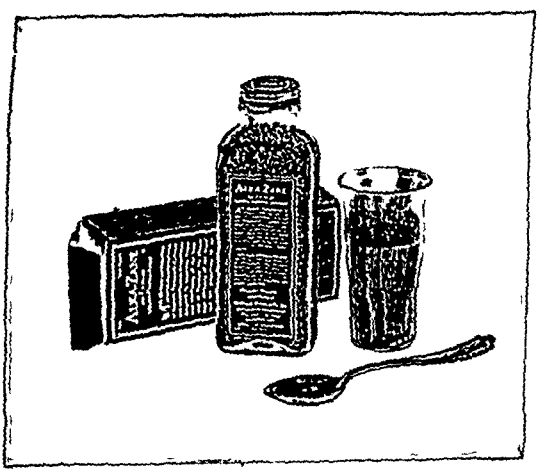
Points of Perfection in the Preparation of LACTOGEN

FREE SAMPLES and detailed descriptive literature of Lactogen and Mono of the Modified Protein upon request, to Nestlé and Anglo-Swiss Condensed Milk Co., 6 & 8 Lutchcap Lane, London, E.C.3



Unvarying Fat Content

Lactogen furnishes a fat allowance comparable to breast milk. The special Lactogen emulsifying process ensures a very fine and widely-dispersed division of the fat globules, so that Lactogen is very easily digested and may be freely prescribed for even the most delicate infant. The fat content of Lactogen is maintained with meticulous accuracy by scientific control of the modification process. Lactogen is a modified dried milk for use in infant feeding—prepared in England by Nestlé's, from the rich, pure milk of selected English herds.

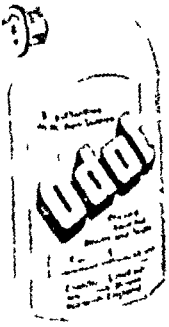
FOUNDED ON THE ROCK OF FACT

During 1930 a number of convincing experiments with Odol were made in Great Britain by well known Dental Authorities.

It was proved that —

That Bacillus Typhosus is destroyed within 10 seconds if Odol is used at a strength of 1 and that Odol will destroy the same microorganism within 2 minutes if used at a strength of 2

It was proved that —



That Odol is unique in respect of the time during which its antiseptic influences remain effective in the mouth The protective power of Odol remain potent in the oral cavity up to four hours after use— and without any injurious effects on the mucous membrane or lime salts of the teeth

It was proved that —

That the nasal and throat passages can be cleansed effectively by Odol and the risk of infective diseases greatly reduced by its regular use

The prophylactic qualities of Odol are combined with a refreshing and agreeable flavour and perfume which your patients will appreciate

Odol enjoys firmly established and increasing prestige with doctors dentists and nurses because they find its claims are founded on the rock of fact

HORLICK'S MALTED MILK

Horlick's Malted Milk is a modified milk which is an ideal diet not only in acute illness and during convalescence, but in the many chronic conditions of ill-health, which are favourably influenced by correct dieting

Physiological tests have shown that the proteins of Horlick's are readily digested and absorbed, and that its carbohydrates are well tolerated

In heart disease generally, and myocardial failure particularly, in tuberculosis, neurasthenia, and other debilitating conditions, Horlick's satisfies the clinical requirements It gives adequate nourishment without burdening the weakened digestive powers of the patient It conserves body tissue and enables rebuilding to be accomplished satisfactorily

Horlick's can also be "fortified," if necessary, by the addition of milk, cream or a beaten-up egg, or by forming an emulsion with olive oil

FOR PATIENTS WHO WON'T EAT—

• BRAND'S INVALID FOODS

for instance Brand's Calf's Foot Jelly

A palatable food is an easily digestible food In cases of illness the value of a food often depends directly on its palatability

Brand's Calf's Foot Jelly is "the real thing," just like the famous Brand's Essences It is the pure meat jelly, delicately flavoured with wine and the juice of fresh oranges and lemons

For a hundred years medical men have valued Brand's Invalid Foods Patients enjoy Brand's even when they can enjoy nothing else, and "l'appetit vient en mangeant"!

Brand's Invalid Foods are British made from entirely British ingredients, and they are all sterilized

other very palatable invalid foods

BRAND'S MEAT JUICE

1 Same high quality as Brand's Essences 2 British 3 *Costs less* 4 Coagulable protein far above average for *pure juice* 5 Many times more nourishing than ordinary extracts as administered

BRAND'S REAL TURTLE PRODUCTS

Brand & Company are one of the few importers of live turtles Often 300 a day arrive in sea water tanks from the West Indies Turtle meat is rich in phosphorus and is easily digested Turtle Jelly and Soups both available

ALSO BRAND'S CHICKEN BREASTS IN PURE CHICKEN JELLY BRAND'S INVALID SOUPS AND BROTHS, BRAND'S BEEF TEA (HOME MADE)

BRAND'S INVALID PRODUCTS

BY APPOINTMENT

(Æsculapius).

Ephregel

A NASAL JELLY

containing

EPHEDRINE & ADRENALIN

for

HAY FEVER & RHINITIS

Ephregel is a convenient means of applying ephedrine to the mucous membrane of the nose, the effects being gentle in initiation and persisting for an appreciable time. The duration of the action is enhanced by the water-soluble base in which the medicaments are incorporated. Its freedom from grease renders it very cleanly in use.

It is suitable for the treatment of nasal congestion in children.

Ephregel is supplied in collapsible tubes, fitted with a suitable nozzle.

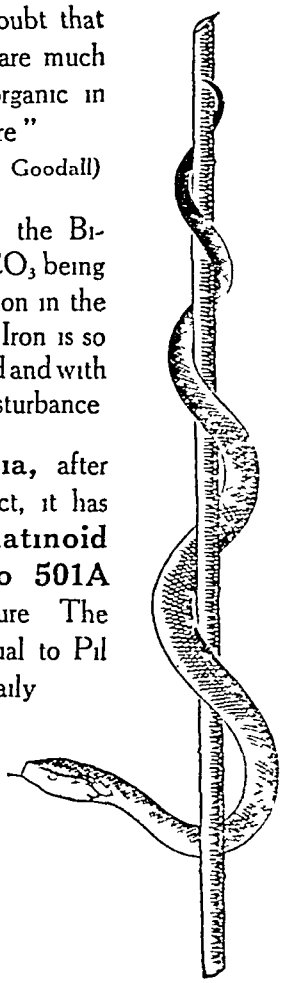
THERAPEUTIC NOTES

from

Oppenheimer Son & Co Ltd



ANAEMIA:

"In Chlorosis there is no doubt that the inorganic forms of Iron are much more efficacious than the organic in bringing about a speedy cure"

The Blood (Gulland & Goodall)

This fact is accentuated in the Bipalatinoid owing to the Fe CO_3 being formed in the nascent condition in the stomach No other form of Iron is so readily and rapidly assimilated and with so little digestive or other disturbance

In Pernicious Anaemia, after treatment with Liver Extract, it has been found that **Bipalatinoid Ferrous Carb,** gr iii, **No 501A** will maintain the blood picture The dose is 3 Bipalatinoids (equal to Pil Blaud gr 15) three times daily

Exempla:

BIPALATINOID No 500

Ferrous Carb gr i = 1 Pil Blaud

BIPALATINOID No 511

Ferrous Carb gr i
Sodii Arsen gr ¹⁄₂₀
Ext Nux Vom gr ¼

Observations
ON
MENOPAUSAL INSANITY AND BACTERIAL TOXAEMIA

BY
T. GILLMAN MOORHEAD, M.D., F.R.C.P.I.
CONSULTING PHYSICIAN, MEATH HOSPITAL, DUBLIN

Focal sepsis as a factor in the causation of mental disease was one of the subjects under discussion at the Annual Meeting of the British Medical Association in Edinburgh in 1927. To this discussion William Hunter contributed the opening paper and reviewed the subject at considerable length. He quoted the experience of Cotton in America and of Graves in Birmingham to the effect that the removal of septic foci frequently led to improvement or complete recovery in cases of even apparently hopeless insanity. Hunter rightly laid stress on the fact that the only test of the part played by a septic focus as a cause of insanity in any given individual was the test of removal of that focus. In the discussion that followed there was by no means general agreement as to the part played by sepsis in mental disorder, and it was pointed out that focal sepsis existed just as frequently in the sane as in the insane. One speaker accused Hunter of arguing from and drawing general conclusions from a single case.

In reporting a case of menopausal insanity apparently due to focal sepsis it is not desired to draw any general conclusions, but as similar cases may exist it appears to be of importance to examine every case of insanity occurring at the climacteric for possible septic infection. At the Winnipeg meeting of the Association in 1930 the nervous and mental manifestations of the climacteric formed the subject of a discussion in the Section of Mental Diseases and Neurology, but in the opening paper no mention was made of uterine or other sepsis as a possible cause of such disturbed mental conditions. The main exciting cause was agreed to be endocrine imbalance. This may be regarded as the orthodox and generally accepted view.

It will be seen in the report of the present case that the existence of uterine sepsis was not at first recognized, nor was its importance realized at an early date. One reason for this was that the theory of endocrine imbalance as the cause of all menopausal insanities was accepted by both the physicians attending the case and that when surgical treatment for the removal of the uterus was discussed it seemed impossible to them that such an operation could favourably influence an insanity the prime cause of which was ovarian deficiency. The existence of uterine sepsis was indeed far from obvious even to expert gynæcological examination, owing to the absence of vaginal discharge. Probably most cases of menopausal insanity are due to endocrine deficiency, but as already stated, on the chance of others being due to sepsis and remediable by the removal of that sepsis, it is thought right to call special attention to the following case.

HISTORY OF CASE

A married woman aged about 50 years came under my care in October 1930. She had been previously well known to me over a period of some years. The history I obtained was as follows. Up to about eighteen months before the beginning of her present illness she had been a perfectly healthy active and cheerful woman. She had had two healthy children—now adults—and two miscarriages. Early in 1929 she began to suffer from irregular uterine bleeding. This led her to consult a gynæcologist who told her that the uterus was slightly enlarged and performed a curettage. Slight if any improvement followed this, and at subsequent examinations a diagnosis of fibrosis uteri was made. Operation was discussed but since the patient was unwilling—the condition not being very severe—operative treatment was not carried out.

During the spring of 1930 some friends noticed that her manner had to a certain extent changed. She was more silent than usual and was apathetic. *In July 1930* she went for a holiday with her husband. During this holiday she suffered from severe uterine haemorrhage and felt very unwell. On her return home she was in fair health till one day she received a severe mental shock in the shape of a telephone message telling her of the illness of a relative. Half an hour afterwards she was found lying on her bed in a semi-conscious state. She was then unable to answer questions and had apparently forgotten everything that had happened to her in the previous few months. She was removed to a nursing home where a tentative diagnosis of cerebral thrombosis was made, though it is probable that the condition was really one of acute stupor. She recovered slowly, and after two months was able to return home, although her mental state was far from normal, her memory being extremely defective. Her voice at this time was clear, but when spoken to she generally repeated what was said to her, *and presented in many ways the phenomenon of* automatism.

In October 1930 as already stated I first saw the patient. At this date she was able to be up daily and to take short walks, but had developed delusions of persecution, was still automaton-like in her conversation, and was greatly depressed. Week by week her condition worsened, outbreaks of irritability and excitement alternating with depression. Finally in December 1930, after a consultation with Dr. Bewley, she was again removed to a nursing home where she remained continually confined to bed for the next ten months.

Dr. Bewley, who was in attendance with me from January to September 1931, describes her condition as follows:

> For most of the time she was unable to speak, and unable to stand or walk. All her muscles were excessively flabby; she apparently did not recognize people. There was dribbling of saliva all the time, constant incontinence of urine and fæces, and her expression was quite devoid of any intelligence. There was sobbing and crying, sometimes nearly all day. She seemed to me quite hopeless.

During these ten months, with the exception of a short period of distinct mental improvement in August, she became from the psychological point of view progressively worse. There was extreme depression, frequent fits of weeping, sometimes extreme restlessness with shouting, hallucinations—especially of sight—and many delusions.

In September 1931 she was seen by an alienist who diagnosed præsenile dementia and gave a very bad prognosis. During the greater part of this time there was frequent incontinence of urine and fæces, her physical condition varying from time to time. At one period she was pyrexial for about a month, the pyrexia probably being the result of thrombosis of veins in the left broad ligament, a thrombosis which extended to the left femoral vein. On another occasion there was a pyrexia of about three weeks' duration with severe stomatitis and one albuminuria, and on a third occasion several septic spots appeared scattered over the body. Gynæcological examination at this time showed that the uterus was somewhat enlarged and softer than normal. From time to time there was slight vaginal discharge, but this was by no means persistent.

In April 1931 the idea was first suggested that a hysterectomy might possibly relieve the symptoms. At this date the diagnosis was one of menopausal insanity due to ovarian and other endocrine deficiency, and it was therefore from a physiological point of view an operation was thought undesirable. Further the patient's physical condition was so poor that it was believed that such an operation would prove fatal.

In October 1931 however the physical condition had improved although there was occasional mild exacer-

parents and Dr FitzGibbon was invited to see the case. He expressed a definite opinion that the operation could be performed without risk and further stated that he thought both the mental and physical phenomena were the result of septic absorption from the uterus.

The Operation

On October 7th 1931 a complete hysterectomy was performed both ovaries having previously been removed at the same time. The excised uterus was found to be in a much more septic condition than had been anticipated. Dr FitzGibbon reported that at operation there were no peritoneal adhesions of any kind. The uterus was retroverted and the parametrium on the right side of the cervix was sclerotic and contracted. The whole of the cervix from the vaginal fornices with the uterus and cervix were removed. The tubes normal both tubes and ovaries were removed. The tubes normal atrophied and ovaries small atrophied. The tubes normal chronic ovaries small atrophied. The tubes normal simple follicular cysts continued some [illegible] wall of cysts 1 to 1½ inches thick. The uterus 4½ inches long [illegible] at 3 inches. The cervix was 1½ inches [illegible] vaginal portion 1 inch super[illegible] Dr Rolette who had an opportunity of seeing [illegible] follow[illegible] specimen immediately after removal reported as [illegible]

The uterus was much larger than [illegible] the enlargement [illegible] to a general swelling rather than [illegible] tumour. There was [illegible] fibroid or other [illegible] tumour. The cavity [illegible] and did not present [illegible] suspect of tubercle. The uterus [illegible] but gave a grey [illegible] colour. The cut surface [illegible] In some of the [illegible] the subject of a [illegible] affecting both the muscle and the endo[illegible] but at most [illegible] To appreciate the degree [illegible] the uterus should be compared with a normal [illegible] which would be about [illegible] walls about ½ inch [illegible] all round with [illegible] vaginal cervix [illegible] walls about ½ inch [illegible] all round with [illegible] path[illegible]

Result of Operation

From the physical point of view the patient stood the operation well and apart from a mild heart attack three weeks later probably caused by small emboli reaching the lungs she made an uninterrupted recovery. The most striking result of the operation however and that which leads to the publication of this note is the fact that almost immediately after the operation her mental condition showed a most remarkable improvement. A week before the operation in experienced almost regarded her condition as one of hopeless [illegible] dementia. Three weeks after the operation she was able to reply sensibly to simple questions. After a week she began to notice her surroundings and to recognize her friends and relatives. In a fortnight there was evidence of returning memory. From that day there has been progressive improvement physically and mentally. At the time of writing, this note five months after the operation the patient is able to go out for daily walks and drives she eats well sleeps well and enjoys the visits and conversation of her friends. She writes short letters can read the newspaper for a short period and her face has recovered its old expression of intelligence. She still tires easily but continues to improve in every respect from week to week.

Discussion

It was unfortunate that in this case no bacteriological examination of the specimen was made but the report of Dr Rowlette formerly pathologist to the Rotunda Hospital leaves no doubt that the condition was one of chronic bacterial infection. Such infection would explain the pyrexial attacks from which the patient suffered and also the venous thrombosis. Further it seems almost certain that the septic condition of the uterus was the cause of the mental symptoms. The actual result of the operation from a therapeutic point of view was more dramatic than it is possible to convey in words. Before the operation the patient was apparently hopelessly insane and was rapidly passing into a condition of complete dementia. Immediately after the operation she began to improve and the improvement as above stated has been progressive.

Dr FitzGibbon to whom the credit of effecting this cure is due holds the opinion that many of the customary phenomena of the menopause can be averted or cured by removal of the uterus even when no infection is present. He believes that in the process of involution of the uterus toxic products are formed in that organ which are absorbed into the blood and give rise to flushings and other symptoms. He further holds that if the uterus is enlarged or fibrotic toxins will be formed in greater quantity than in normal individuals and that more serious menopause symptoms are therefore likely to arise in these cases. He is a strong advocate of performing hysterectomy in all menopause cases when the uterus is enlarged and in all cases when menopausal symptoms are severe.

To me Dr FitzGibbon's view is entirely novel and my own belief is that the cure brought about in the present case was due to the removal of a definitely septic focus but the result was so remarkable and the operation so easily borne that I feel it would be worth while giving a thorough trial to Dr FitzGibbon's views in all cases of menopausal insanity provided the services of an expert gynaecological surgeon can be obtained. The case at any rate suggests the advisability of dealing radically with all foci of septic infection in cases of menopausal or other insanity.

THE MENOPAUSE AND ITS COMPLICATIONS

BY

CIBBON FITZGIBBON M.D. F.R.C.P.I. F.C.O.G.

GYNAECOLOGIST ST PETER'S HOSPITAL DUBLIN

The case of menopausal disturbance cured by hysterectomy recorded by Dr Moorhead (p. 923) in which the condition of the patient was compatible with a diagnosis of senile dementia should suggest that the generally accepted ideas on the menopause are not quite correct. Dr Moorhead indicates that I place a different interpretation on the clinical symptoms generally supposed to be due to the menopause from that usually accepted. It was owing to these views that I expressed the opinion I did in Dr Moorhead's case and in this paper I wish to propound and as far as possible explain my own views for that purpose I must give my summary of the case which was an extreme one of its type but my beliefs are not in any way based on it although it adds considerable support to them.

Dr Moorhead's Case

I have been personally acquainted for many years with the patient. She was married when 22 years of age and had one child soon after marriage. She acquired a retroversion of the uterus after her confinement and had two early abortions and a second child seven years after marriage. The uterus then remained in retroversion. There was evidence of septic infection at her confinement but this cleared up and the patient subsequently led a normal active healthy life. The monthly periods were always of the heavy type and became more so from the age of 45 this as usual was considered to be associated with the approach of the menopause.

When 49 years of age curettage was performed on account of the menstrual loss but without benefit. The uterus was found to be retroverted and enlarged. The possibility of a fibroid was considered as well as hysterectomy this was not done as the existence of a fibroid was very doubtful and the monthly periods continued to occur regularly. At

this time the patient had considerable domestic responsibilities which she willingly assumed and always appeared indefatigable

In July 1930 at the age of 51 she received a shock and collapsed into a condition suggestive of a brain lesion This was the beginning of her illness as described by Dr Moorhead *The monthly periods continued regular but heavy until* January 1931 when a period of amenorrhœa set in and continued for six months Then vaginal discharge appeared and the uterus was douched a moderate degree of haematometra being discovered and removed The next monthly period occurred after twenty eight days it was profuse but not prolonged A few weeks after this I first saw the patient I found the uterus in retroversion it was enlarged to three or four times the size of a normal non pregnant uterus the vaginal portion of the cervix projected about three quarters of an inch into the vagina and the supravaginal portion was very bulky giving an indurated non elastic resistance On the right side the parametrium was hard and indurated making palpation through it difficult There was a fairly profuse viscid leucorrhœal discharge with a very slight if any purulent element In my opinion there was sufficient evidence of chronic induration of the supra *vaginal cervix and surrounding parametrium for* these parts to be the centre of a chronic toxic absorption capable of producing a very considerable degree if not the whole of the patient's general and mental debility This opinion was based on my observations of the enormous improvement in the physical and mental state of several patients upon whom I had performed hysterectomy for very similar uterine states causing disturbance at or after the time of the menopause and particularly of the two cases to be described

TWO OTHER CASES

1 *A married woman aged 66 years last confinement at age* of 26 was referred to me on account of slight but persistent haemorrhagic discharge from the vagina Menstrual bleeding had ceased at the age of 52 Shortly after this she had lost a son during the great war and since then had lost interest in everything had developed a mild melancholia complained of very *little objected to interference* and seemed merely to wish to be left alone The uterus was removed by vaginal hysterectomy Six months later I learned that my patient had resumed all her former social activities and enjoyed seeing visitors paying visits going to entertainments and even going for trips from home

2 A widow aged 48 years with one child 16 years old had for the past two or three years suffered from debility supposed to be due to menopausal bleeding She was described by her relations as doing nothing but mope after her son Five months after a hysterectomy had been performed she had assumed a cheerful mental aspect quite different from her former state taking a keen interest in life generally and enjoying outdoor sports

I was much impressed by the physical and mental change in these two patients Both had small fibroids of the uterus which ultimately indicated treatment by hysterectomy but in neither was the uterine bleeding sufficient to produce the degree of physical and mental depression from which they suffered In the former the menopause was delayed but no bleeding had occurred for ten years and then it was only a stained discharge In the latter the menstrual loss was heavy there was some anæmia but not sufficient to make the patient seek advice The removal of the whole uterus was followed in a short time by an unexpected and remarkable improvement in the physical and mental well being of the patients

On following up other patients treated by total hysterectomy during or after the menopause I found similar marked improvement in the general and psychological conditions I have subsequently performed hysterectomies on a number of women suffering from persistent ill health of the varying type diagnosed as neurasthenia at the time of the menopause and operation has been followed by complete restoration to health and well being

OBSERVATIONS ON DR MOORHEAD'S CASE

To revert to Dr Moorhead's case I wish to emphasize several facts that are commonly present in the type of case with which I am dealing

1 The patient had borne children shortly after marriage and then passed a long period of sterility continuing until the time of the menopause One of her confinements was complicated by a septic infection which ultimately cleared up and although the uterus remained in retroversion her pelvic state did not apparently influence her health adversely This condition is a basic factor in the development of the subsequent disturbances but owing to the remoteness of its acute period and the long interval of apparently good health it is quite forgotten and overlooked at the time of the menopause It naturally occurs most commonly in women who have borne children but is not restricted to them It may develop in childless women or in women who have never had any complication in their confinements as a terminal chronic state of other septic infections of the cervix *parametrium and uterine appendages and—as in the two* cases recorded above—as the result of the presence of fibroids of the uterus which in themselves were causing little disturbance

2 The patient from the time she reached the age of 43 or 44 and so had entered that stage of existence usually termed the period of the change of life had serious responsibilities cast upon her which induced her to take little notice of her own state of health and to disguise her disabilities From the acceptance of the *common* belief that these were only part and parcel of what every woman has to expect for a few years at her age she overcame her physical deficiencies by will power hoping that in a few years she would once more be fit This again is a common incident in the life of many women as they reach the forties Family social or assumed duties have increased and they are reluctant to admit that these are burdensome They feel that to do so would be to admit old age They see many other women older than themselves easily able to do what they find burdensome and therefore they disguise the facts but frequently develop an irritable and morbid temperament although fulfilling—and to the outside observer well able to fulfil—their duties

3 The onset of the patient's illness was apparently sudden It is a very common termination at the ages from 48 to 52 in women who have been suffering from menopausal disturbance for several years They develop some trivial illness this is followed by debility altogether out of proportion to the illness which persists in spite of treatment The nature and intensity of symptoms vary and lead to variation in diagnosis which in the milder cases often ends in a final diagnosis of neurasthenia or menopause neurosis with the deferred hope that health will be restored when the menopause is complete

4 Six months after the patient's breakdown the monthly periods ceased and remained absent for six months there was little improvement as the result of this the general debility was slightly diminished At the beginning of the period of amenorrhœa the possibility of a uterine origin of the whole trouble was considered but abandoned owing to the termination of the menstrual cycle uterine symptoms and the appearance of slight improvement Uterine bleeding again started and the patient's condition had become comparable with a diagnosis of severe dementia præcox and progress was Her mental state extreme degree of depression characterized a mild case The women have been treated that health will be attained again when they are through the change of life Some of them find that when the monthly periods have finally ceased their general health does not improve—rather it

feel worse. They are then left without the hope of ultimate recovery of health and fall into a chronic state of debility and depression without interest lacking in energy a nuisance to themselves and their families and generally spoken of as "poor So and so".

The cases reviewed above were one of extreme physical and mental disturbance developing in association with the menopause and the fact established that the disturbances were terminated by the performance of a total hysterectomy. We consider these symptoms due to the normal physiological change of the menopause or were they the effect of a pathological condition brought into activity by the menopause? This question can be answered by a review of the menopause in a normal individual and the whole course of the active genital period of a woman's life up to it.

The Normal Menopause

Physical and mental alterations in the character of women are extremely common at the time of the menopause, such that they are looked upon as necessary results of that change. They vary from profound and permanent lack of all health to light and transient disorders. Women suffering from these disorders rest and obtain from them advice to the notice of their friends and the medical profession thus setting a standard for the exclusion of the characteristic suffering of that change in a large group of women who do not suffer.

If a large number of women who had reached the age of 50 years could be examined without selection they could be divided into the following groups:

1. (*a*) A large group comprising both parous and non parous women who, monthly period having already ceased and who have at no time experienced any inconvenience or disturbance. They would state either that their period stopped suddenly having been previously normal or that their period had gradually diminished and ceased to reappear slightly once or twice in the next six months and then disappeared completely. Such women are invariably active, healthy and young looking for their age.

(*b*) A moderate group of women whose periods still continue with little alteration or disturbance.

2. (*a*) A small group of women chiefly parous whose periods have ceased but who before the complete termination had for a year or more experienced excessive loss and resultant debility while some had towards the end a few prolonged intervals and floodings. Such women will have returned to good health dependent on the length of time that has elapsed in which they can recuperate.

(*b*) A moderate group of women whose periods persist but are and have been for some years heavier than normal. They suffer varying degrees of ill health and loss of energy. Many of these women will follow the course of those above but quite a large number will follow the course of those in Group 3 (*b*).

3. (*a*) This is a very small group—chiefly persons whose periods have ceased after several years disturbance and general ill health but whose ill health has persisted or even increased.

(*b*) A group of women whose periods after several years of excess have become irregular and often prolonged and whose general health is seriously degenerated. The aberration of the menstrual cycle will call for attention the menopause will be completed by operation or degeneration will progress and terminate under various nomenclatures or even fatally.

4. In addition to these groups there would be a number of women who on account of marked disturbance in the menstrual function after the age of 40 were found to have tumours or other gross pathological conditions of the genital organs and in whom the menopause was induced by operation.

It seems unreasonable to assume that all the first three groups are merely variations of a normal physiological process while the need for operative treatment arose in the fourth group from an accidental pathological lesion unassociated with the menopause. It appears more logical to conclude that the characters exhibited in Group 1 are those of the normal physiological process. Those of Group 2 are slight aberrations from the normal induced by pathological lesions while those in Group 3 are definitely the outcome of pathological lesions quite as much in need of treatment by operation as was found necessary in Group 4. A review of the child bearing period of a woman's life seems to justify this assumption.

The age of puberty may to some extent be compared to the age of the menopause—they come at the extremes of a woman's reproductive life. In the one there is a hypertrophic change often in previously damaged other an atrophic change in healthy tissues in the tissues. Taking large groups of girls—for example in schools—it is quite an exceptional event to find marked physiological or psychological disturbances developing at the age of puberty and such cases as do occur are nearly always found to be due to some definite pathological condition or gross developmental abnormality. The vast majority exhibit progressive development for two or three years without any disturbance in general health. By analogy it seems reasonable to suppose that the atrophic tissue changes taking place at the menopause should be spread over a period of years that slight variations in the local manifestations of cessation should occur that the atrophy should continue over a period of one or two years and that menstruation should finally cease without any or with only slight disturbance. A very large number of women do follow this course but as the menopause is a process of atrophy and in many cases the organs have suffered damage or change from the normal state a large number will exhibit faults in the physiological process.

The Age of the Menopause

The age of women when the menopause is completed as defined by the cessation of monthly periods ranges from 40 to 55 years but a number of facts seem to indicate that the atrophic changes commence in the vast majority of women within fairly restricted limits of age probably from 42 to 46 years. How long the atrophy will take to become complete varies and depends upon the physiological state of the health of the organs.

On investigation of the ages of 1 700 women confined in the Rotunda Hospital it was found that only thirteen women were 49 eight 44 and five 45 years of age. During seven years out of 12 500 confinements there was only one woman aged 47. There was no woman over 45. These women are of a class who do not avoid pregnancy and even allowing for the attrition of advancing years the falling off in the power to conceive after the age of 45 is too great and indicates some change preclusive of conception. That this change is one involving the uterus and endometrium rather than the ovaries and the process of ovulation is suggested by the facts that the sexual habits and desires of women are not diminished at the time their power to conceive has ceased and that at operation on women at this age the ovaries are usually found normal in appearance and containing normal corpora lutea. In an analysis[1] of cases of fibroids of

the uterus treated by operation in the Rotunda Hospital during seven years it was found that the majority developed symptoms calling for attention about the age of 45 although other facts indicated that the fibroids had been in existence for upwards of ten years This suggests that the fibroids are not the cause of the symptoms but that the symptoms are the result of some change which develops about the age of 45 in the surroundings or the nutrition of the tumours

The above facts seem to indicate that as puberty normally occurs between the ages of 13 and 16 so the menopause normally begins between the ages of 42 and 46 and should normally be completed in two to three years without disturbance of the general health

The Size of the Uterus

The fully developed nulliparous uterus is described as an organ three inches long with a cavity of two and a half inches and after childbirth it is supposed to retain a general increase in size This latter statement is correct in a very large number of instances but that it is a normal outcome of childbirth is doubtful If a woman who has had an easy spontaneous labour without puerperal complications is examined six months later and the uterus is found in a normal anteverted position the latter will present no appreciable difference from the nulliparous organ—the external os is slightly relaxed but the cervix is no more bulky and the cavity is only two and a half inches long Such women are not often examined except in immediate association with a pregnancy During the *menopause* and for some years after the termination of menses the uterus undergoes atrophy and a considerable reduction in size How long this change takes to be completed in a normal case has never been even approximately estimated nor has it been established to what size a normal uterus should return That the body of the uterus undergoes a marked diminution in size is clinically evident and also that the vaginal portion of the cervix ceases to exist [2] while the narrowing of the vaginal vault indicates that the supravaginal portion of the cervix is also reduced The cavity of the uterus is smaller in all directions This would appear to be the normal course

Criteria of Normal Menopause

The normal character of the menopause and the condition of the uterus may be thus summarized

1 The menopause consists of an atrophy of the genital organs from the developed state adaptable to child bearing to a state closely resembling that of the organs preceding puberty

2 This change should occur without either physiological or mental disturbance

3 It normally commences between the ages of 42 and 46 and is completed within two or three years There are normal exceptions on both sides of these ages

4 The uterus at the beginning of the menopause should be little if at all larger than the uterus of a young nulliparous woman—that is three inches in length with a proportion of body to cervix of two to one and the cavity two and a half inches long

5 When the atrophy of the menopause is complete the uterus is considerably reduced in size in all its parts being two to two and a half inches long with a cavity one and three quarters to two inches in length and no vaginal portion of cervix

Pathology of Uterus at the Menopause

Women at the time of the menopause may be divided into three groups—virgin nulliparæ and para They are all liable to have developed pathological conditions during the child bearing period but with increasing frequency in the order of the groups All groups may have congenital lesions but these do not influence the menopause—with the exception of retroversion Retroversion in some nulliparous women appears to produce in the process of time a hyperplasia of the uterus This is probably the result of excessive congestion at the menstrual periods causing excessive flow which associated with defective drainage stimulates uterine action and produces muscle hypertrophy

In the group of virgins the incidence of fibroids is the chief factor, these are always associated with hypertrophy of the uterine muscle and may in time be extruded outside the muscle becoming subserous The muscle may undergo involution but if this does not occur the uterus remains in a state of hyperplasia at the time of the menopause If the fibroids become submucous they produce discharge and promote the tendency to chronic infection which frequently involves the cervix causing chronic cervicitis The secondary results of retroversion also lead to chronic infection of the same sort as shown by the common association of erosion There are thus in the virgin two common potent causes of metritis and cervicitis which are of long standing and persist at the time of the menopause

In the nulliparous group there is added the common incidence of ascending infections independent of either fibroids or displacement

In the parous group the risk of acquired lesions is enormously increased Besides all those of the other groups there is the frequent occurrence of acquired or post partum retroversion In an investigation of 100 women after normal uncomplicated confinements twenty seven were found to have retroverted uteri six weeks post partum and nine of these had retroversion before they became pregnant Retroversion of the uterus whether acquired or a return to the congenital condition is practically always associated with subinvolution which persists and becomes a chronic hyperplasia if the retroversion is not corrected while the subinvolution is in an acute or subacute stage This practice is far from common and the retroversion is allowed to persist It is a common cause of one child sterility if it occurs once it will recur after all subsequent pregnancies Although it does not often cause symptoms during the living in period it develops about the ninth day and seriously interferes with the free drainage of the uterus during the remainder of the puerperium It is a potent cause of low chronic infection productive of chronic metritis and cervicitis Lacerations of the cervix especially those involving tissue above the vaginal portion add the devitalizing effect of prolonged pressure on the cervical tissues in protracted labour promote the chances of infection which although of a low type calls for no observation during the puerperium is the cause of the indurated enlarged cervices so commonly found in parous women

The causes of pathological states of the uterus at the time of the menopause may be summed up as follows (1) ascending infection promoted by stagnation of normal or other discharges from the uterus and cervix (2) laceration and damage during childbirth of the cervix and parametric tissues exposing these tissues to chronic infection (3) septic infection following childbirth (4) gonococcal infection upon which secondary infection supervenes—far less common than of yore and (5) growth and influence of ovarian stimulation on fibroids The pathological lesions which are produced and influence the course of the menopause are (1) chronic hyperplasia of the body of the uterus (2) chronic

metritis with chronic cervicitis and (3) chronic cervicitis with or without parametric induration. A cervix with these conditions therein is an increased vascularity the smaller uterus are hypertrophied and there is venous congestion.

During the active child bearing period of life these lesions produce varying degrees of leucorrhoea calling for palliative treatment such as routine douching, application of caustics and curettage. These treatments have no more curative effect upon the chronic infection than a splash in chronic tonsillitis. Amputations of the cervix often cure when the portio vaginalis is the part involved but they frequently stop far short of removing the main centre of infection which is the supravaginal portion. When the period of the menopause is reached and atrophy of tissue is being proceeded the vitality of the tissue is reduced and the production of toxins from the chronic infection is increased. The local condition leucorrhoea has been accepted as inevitable while more or less menstrual loss relieves the woman at the time but is considered a normal part of the menopause.

Effect of Pathological Lesions on the Menopause

The simple lesion of chronic hyperplasia commonly three to five portion to recovery or associated with blood. The over-stimulation of the ovarian tissue has to end in atrophy. There is therefore a prolongation of the process with excessive strain at the period and resulting debility but a normal the completion of the process is not prevented. When the atrophy is finished the uterus remains larger than it should be being about the size of a nulliparous uterus and the woman recovers from the temporary debility. Sometimes the menstrual losses are so profuse as to call for treatment and curettage is found to give temporary relief which help to tide matters over. In others the loss is sufficient to call for more active treatment and excellent results are obtained by x rays or radium. This is the lesion that exists in the second group of women previously described as seen at 50 years of age.

The most pronounced lesion is chronic metritis with chronic cervicitis. There is always hyperplasia this varies in amount and is often very marked. This lesion during the process of atrophy produces all the symptoms due to hyperplasia and varying in proportion with it but the symptoms are increased by the added element of toxic absorption. When the atrophy is complete the menses may cease or become irregular but the general health does not improve and often further deteriorates. This is the lesion that exists in the third group of women at 50 years of age. Various treatments short of total hysterectomy are resorted to for the menopause and are credited with being of benefit if the menses terminate irrespective of the permanent loss of fertility in the women quite inconsistent with their age. These are the cases that do not give satisfactory results with x rays and radium. This is to be expected as they contain the chief contraindication to this treatment—septic infection. As this is not obvious it is overlooked and this lesion is only excluded from x ray treatment when it is accompanied by evidence of chronic pelvic peritonitis parametritis and adhesions.

The third lesion—chronic cervicitis—may be associated with simple hyperplasia when the local symptoms referable to that will be present and follow the course already described but the general symptoms will be increased. When hyperplasia is not present the menopause so far as the menstrual cycle element is concerned is passed uneventfully but there is an unaccountable element of not well being. This not well being continues after the menses have ceased and may ultimately die out with no permanent ill effects but many women show premature ageing and if the infection does not die out their ill health persists. Women with this lesion come under Groups 2 (*a*) and 3 (*a*) at the age of 50. Of the various treatments adopted for this condition x rays and radium have the same influence as in the other lesions but diathermy needs to be especially mentioned. Its application may hasten and even promote the dying out of the infection when this is limited to the portio vaginalis but when the infection extensively involves the cervix and especially when the parametrium is affected its action is not sufficiently penetrating.

Summary

All through this paper reference to any individual symptom of the menopause has been avoided as a whole they are too various and undefined, with the exception of flushings and sweating. These two are much the least important they are probably as near as an abnormality can be to a natural incident. They are probably wholly of ovarian origin and occur in women who pass through an absolutely normal menopause but in the women they more often arise after the menses have ceased and are seldom sufficient to call for more than transient notice and an assurance that nothing serious is wrong. It is when they are associated with the conditions considered in this paper that they are increased and call for serious comment and are so often intractable to treatment. They respond to all sorts of treatments which improve the general health and relapse when the general health deteriorates.

The writer is in no sense advocating hysterectomy as a universal treatment for ill health at the time of the menopause. The differential diagnosis of the lesions described is a difficult and minute matter. It is seldom possible to make an early decision—such cases are mentioned in Group 4 of women at 50. In the majority of instances a decision will be reached only after a period of observation but the lesions which exist at the onset of the menopause can be observed and should be sufficient to indicate treatment by hysterectomy if the ill health increase. Serious and permanent damage may thus be prevented. When hysterectomy is resorted to it must be of the total type. I believe that the failure to observe the benefits of hysterectomy in these cases has in the past resulted from the common practice of performing the high partial operation this relieved the menstrual symptoms but did not remove the toxic element.

Conclusions

1. The menopause should occur with as little disturbance as puberty.

2. During the child bearing period of life many women acquire pathological lesions of the uterus which frequently induce chronic bacterial infection of the uterine body and cervix.

3. When the atrophy of the menopause occurs the toxic influence of the infection is stimulated.

4. The pathological lesions delay and disturb the normal course of the menopause.

5. The toxic absorption causes ill health and frequently persists after the menopause is completed.

6. If the aberration of the menopause or the toxic effects are severe treatment by total hysterectomy is indicated to prevent permanent damage to the future health.

PHOTOTHERAPY IN ERYSIPELAS

BY

J M DAVIDSON M D D P H

ED BURGH

Much has been written and continues to be written regarding the treatment of erysipelas each new remedy enjoying a passing popularity only to be discarded in favour of the next The mere multiplicity of methods itself testifies to their inefficacy or their lack of universal applicability and indicates the need for further experiment Local applications used empirically, have largely given place to attempts at specific therapy mainly in the form of serums and vaccines but while this would appear to indicate a distinct advance it is generally admitted that wide variations in the response to antitoxin and vaccine therapy exist

In these circumstances I feel justified in submitting records of the following cases and advocating on deductions drawn from their study the early employment of ultra violet radiation as a means by which practically all cases may be advantageously treated The series consists of fifty one cases for the most part consecutive treated at the Edinburgh City Hospital

Literature

Although records of the treatment of erysipelas by ultra violet rays have been published by a few Continental and later American writers workers in this country appear to have altogether neglected the investigation of this line of attack

Koenig[1] was one of the first to experiment with this mode of treatment having employed it as early as 1919 using a quartz mercury vapour lamp While admitting its efficacy in certain cases he pointed out that in others it failed to attain the desired object Later Petersen[2] treated fourteen infants suffering from erysipelas in a similar manner and although two of his cases in which treatment was commenced at a late stage died the remaining twelve recovered All his cases were under 10 months three of those surviving being newborn infants with umbilical infection Considering the usual death rate of erysipelas in infants these results were remarkably good He specified dosage simply in terms of time and distance from the lamp used his commencing dose being less than that necessary to produce an erythema Cruise[3] in 1922 reported a series of one hundred cases treated thus and in almost every case the temperature fell promptly after the first irradiation and the spread of the inflammation ceased His results he says were so constant that they cannot be attributed to chance Brunauer[4] attributes the varying results obtained by previous workers in this field to the variable methods in which the treatment was applied He recorded fifteen cases treated thus his technique differing from that previously adopted in that he covered the centre part of the lesion and irradiated only the spreading edge His results were good

Becker[5] also using a mercury vapour lamp recorded two cases in which actinotherapy had immediate good results and recommended exposure to one and a half times the erythema dose of an area extending 4 cm beyond the erysipelatous area in all lines Later he reported that in eight infants ranging in age from 18 days to 12 months with erysipelas treated by means of ultra violet radiation with one and a half times the erythema dose only one death occurred and that was in an infant aged 20 days in whom erysipelas followed operation for umbilical hernia

Hess[6] in Minneapolis in an interesting and instructive report implies the results obtained in treating a large number of cases of erysipelas by various methods his conclusions being that the various methods used give practically the same end results with some slight advantage to the ultra violet rays The dose employed was one that required to produce a mild erythema normal skin—less than the sunburning dose Later Hess and Paton[7] recorded very good results in a long series of cases adopting precisely the technique employing the same technique and dosage

Results in a Series of Fifty one Cases

In the series of cases to be described the source of ultra violet light was a standard model air cooled quartz lamp The efficiency of the lamp was tested by estimating the erythema dose for a series of patients with the arc at a fixed distance of 12 inches from the skin surface In practically all the cases following an exposure of two and a half to three minutes at this distance a mild but definite erythema resulted In a few of the cases under consideration the individual erythema dose was estimated before treatment was commenced but as individual differences in response at such short range proved to be very slight and as such a preliminary investigation entailed deferring actual treatment two and a half to three minutes was assumed to be the universal erythema dose except in the case of infants For actual treatment one and a half times to twice the erythema dose was employed In all cases before estimating the erythema dose and before commencing treatment the lamp was allowed to burn for at least five minutes to ensure as far as possible constancy of output

Technique of Treatment

Before treatment was commenced any soothing preparation previously applied to the part especially if greasy was carefully removed from the affected area and surrounding skin All cases except infants were exposed for five minutes with the arc at a fixed distance of 12 inches In the case of infants a slightly shorter exposure was employed when the actual individual erythema dose was not estimated In all cases part or all of the inflamed area according to its extent was included in the exposure with a margin of about ½ inch of healthy skin when this was possible the rest being protected by some light covering In facial and head cases generally the eyeballs were protected by small pads of cotton wool fixed by a narrow strip of adhesive plaster but the eyebrows were left uncovered and each part of the spreading edge was systematically exposed to rays falling as far as possible perpendicularly When the entire involved area was easily covered by one exposure this completed the treatment but occasionally part of the lesion which at the time of admission was assumed to have subsided was neglected and had to be treated later In the few cases in which definite extension occurred through the erythematous area the treatment was repeated one or two days later if a margin of healthy skin could still be included Following light treatment the affected part was left uncovered or at least without dressings except in two instances in which pain was a prominent feature and in these lint wrung out in cold water and frequently renewed was sufficient All other treatment was symptomatic

The cases treated ranged in age from 7 months to 74 year and included primary cases and cases [illegible] to accidental wounds operation wounds and contusions As usual there was a marked preponderance of facial cases

Subacute cases showing no evidence of [illegible] constitutional disturbance were not treated and are excluded in the series Table I shows the ages and sex [illegible]

TABLE I [illegible]

| Sex | Age in completed Years | | |

Immediate Effects

During the exposure the patient in no instance complained of discomfort. On the contrary, the sensation of warmth produced appeared to be appreciated. In the course of a few hours the healthy skin included in the radiation area showed an intense erythema with a degree of oedema, the appearance being so similar to that of the erysipelatous area as to render the edge of the latter at times indistinguishable. Later, oedema of the actual lesion was slightly increased. At this stage, as a rule, there was no complaint of pain, even when, as occasionally happened, there was a crop of tiny vesicles on the affected area or an oozing of serum. Local applications were unnecessary. By the end of forty-eight hours the oedema had generally abated, and the affected skin became dry and wrinkled. By this time also there was a critical fall in temperature in thirty-one of the thirty-nine cases in which the whole edge of the lesion was included. In twenty-three of these cases the fall commenced within twenty-four hours. The further course of case was for the most part uneventful.

With the dose adopted—up to twice the normal erythema dose—vesiculation following irradiation seldom occurred, and when it did appear it was of no additional clinical importance, the course of the illness in only one case being modified. In this exceptional case the production of vesicles in a crop of purpuric appearance and of extraordinary profundity, affected the whole of both cheeks and parts of the face.

Ultimate Effects

To gain a true conception of the value or otherwise of radiation therapy it was essential that the cases treated should be adequately controlled. This was done by selecting for each case treated a similar case treated by other means. In allocating controls the hospital records for the past five years were searched, special attention being paid to a consideration of age, sex, localization and extent of lesion, duration of illness, and complications present. In all cases it was found possible to allocate a suitable control.

In assessing the therapeutic value of phototherapy employed this attention was paid to (1) the duration of the pyrexia, (2) the extent of spread of the lesion after treatment, (3) the incidence of complications, and (4) the occurrence of relapses. The mortality rate in such a short series of cases is of little value. Of fifty-one cases treated four died—all complicated cases. The first was a child of 13 months on whom a mastoidectomy was performed after the onset of erysipelas and before phototherapy was commenced; the second death occurred in the case of a female aged 30 with concurrent pneumonia and nephritis; the third was a case of puerperal septicaemia and pneumonia; and the fourth was a female aged 55 already under treatment for severe cardiac decompensation who died suddenly from cardiac failure.

Duration of Pyrexia.—The forty-seven cases treated and ending in recovery were of varying degrees of severity, and in estimating the effect of treatment the temperature chart was taken as the safest single guide, the disease being presumed to have ceased on the day on which the morning or evening temperature was first subnormal and did not subsequently rise except in the presence of an obvious complication. In some of the cases only one section of the spreading edge and neighbouring skin was irradiated; in others a margin of healthy skin all round the inflamed area was included in the exposure, and in the remainder the whole lesion together with the surrounding skin was irradiated.

The results of treatment are briefly summarized in Table II.

TABLE II.—*Duration of Pyrexia in Cases Ending in Recovery.*

Series	Duration of Illness before Admission (Days)	Average Duration of Fever (Days)	Average Duration of Fever after Treatment (Days)
47 cases treated by U.V. rays	3·96	7·81	3·85
47 controls	4·10	9·26	5·16
In the 39 cases in which it was found possible to include the whole of the spread in each the results were as follows:			
39 cases treated by U.V. rays	3·72	6·97	3·25
39 controls	3·91	9·03	5·12
In 23 cases in which the whole affected area and a surrounding margin of healthy skin were irradiated the results were even better:			
23 cases treated by U.V. rays	3·43	5·53	2·10
23 controls	3·31	7·92	4·61

Similarly of eight cases in the series in which treatment was commenced early in the disease—on the second day of illness—the average duration of fever was again 5·5 days as against 9·6 days in the corresponding control cases.

Extent of Spread.—Definite spread of the dermatitis through the irradiated area of healthy skin occurred in a few cases, principally in those cases in which treatment was commenced at a comparatively late stage and the lesion was obviously very active. This was noticed particularly in cases of the wandering type when two or more exposures of the spreading edge at intervals of two days were necessary before spread was arrested.

Incidence of Complications.—The sole complication seen in cases treated and surviving was streptococcal abscess which occurred in two cases.

Incidence of Relapses.—Relapse occurred in one of the forty-seven cases. The inflamed area was promptly re-irradiated and the condition subsided completely within twenty-four hours of the onset. In another case not included in the series in which the initial attack in spite of serum therapy lasted seventeen days there were four relapses. The first occurred thirteen days after the temperature had reached normal and the temperature remained elevated for a further six days. Eleven days later another relapse occurred and it was decided to try actinotherapy. On this occasion the patient ran a mild temperature for only forty-eight hours. Ten days later she again relapsed and was promptly irradiated this time without any recorded rise of temperature. After a further ten days a final extensive relapse took place and under actinotherapy the temperature was again normal within three days.

A brief account of a case in which the erysipelas commenced while the patient was in hospital is interesting. The patient, a female aged 34 years, was convalescent after diphtheria. The erysipelas commenced on the twelfth day in hospital and on the morning of the thirteenth day involved both cheeks, orbital regions and glabella. There was considerable oedema with numerous small vesicles on the affected area and a rapidly advancing well-marked edge all round the lesion. The patient was markedly toxic and confused. The affected parts were subjected to three exposures of ultra-violet light at one sitting—one to each cheek and one to the glabellar region—on the afternoon of the second day, with gratifying results. No further spread occurred, the common feature in such cases of oedema of the external auricle failed to appear, the mental condition improved forthwith, and there was a critical fall of temperature.

From these results it would appear that if acute cases of erysipelas come under treatment sufficiently early prompt exposure of the affected part to what is customarily considered an overdose of ultra-violet rays would in a large proportion of cases abort the lesion. The method also has the advantage of being easily applied and of effecting a considerable saving of dressings and

linen as no local applications following treatment are necessary or indeed desirable A dosimeter is unnecessary If the operator takes the trouble to estimate at regular intervals the efficiency of the lamp used the erythema dose for the individual is easily and quickly ascertained and even when this is not done but the dosage gauged from previous experience with the lamp in use there is a wide margin of safety

SUMMARY AND CONCLUSIONS

1 A report is presented on fifty one cases of erysipelas treated by exposure to an artificial source of ultra violet light the exposure being one and a half times to twice that required to produce a definite erythema on normal skin

2 The treatment of erysipelas particularly the early case by ultra violet light appeared to give better results than other methods in use

3 The method is easily applied usually available devoid of danger cleanly and inexpensive

4 The technique is simple and can be carried out with any ultra violet lamp of known efficiency

The cases detailed are from the records of the Edinburgh City Hospital The opportunity for and inception of this investigation are due to Dr W I Benson superintendent of that institution to whom the writer is much indebted

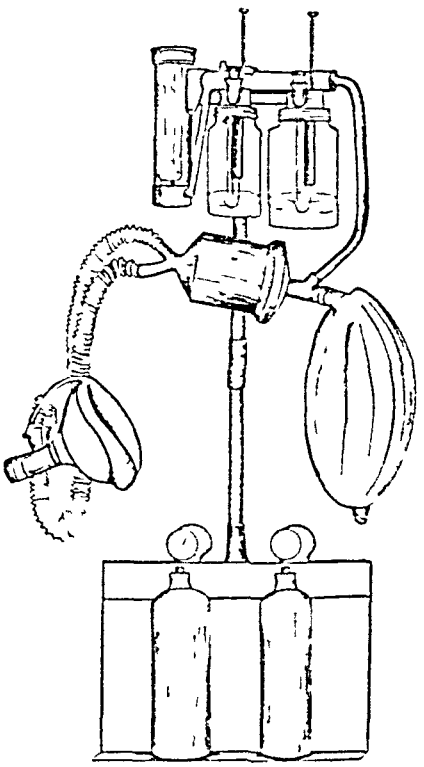
CARBON DIOXIDE ABSORPTION METHODS IN ANAESTHESIA

BY

FRANKIS T EVANS MB BS

ANAESTHETIST ST FAITH'S REVIEWS HOSPITAL



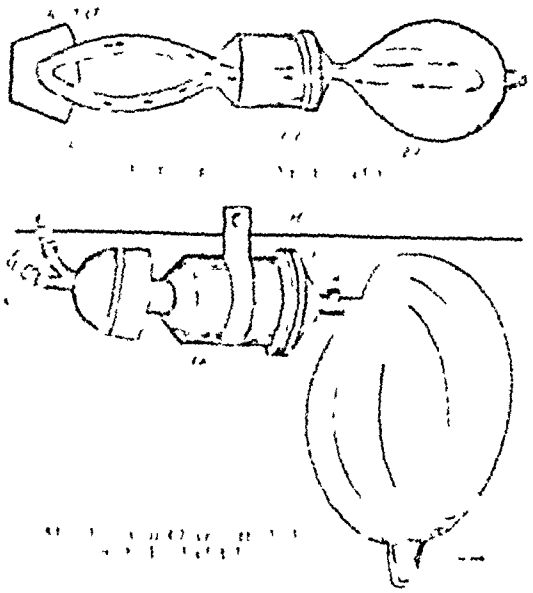
Nitrous oxide and oxygen is now so universally used that the anæsthetist has to transport an apparatus of considerable bulk and enormous weight It was in an attempt to find a really portable apparatus that a trial of the carbon dioxide filtration method was decided upon This method has many advantages and as far as can be seen no disadvantages

In the past carbon dioxide filtration had fallen into disrepute owing to the large size of the canister and the fact that it was bulky and awkward to hold right up at the face piece Nowadays all this is changed by the use of wide bore Siebe Gorman tubing with flap valves to ensure the unidirectional flow of expired gases This enables the absorber unit to be attached to the anæsthetic stand head of the table or gas machine itself while the application of the mask to the face is no longer a wearisome task By means of this unidirectional method of flow of respired gases the absorber canister need not be the bulky apparatus of the past Much experimental work has been done on this method in America by Lundy Heidbrink Company and Foregger Company and McKesson to mention a few so that it is by no means an innovation Hewer also employed the method some years ago in this country In the writer's opinion however the success of the apparatus lies (1) in the unidirectional method of flow (2) in the dead space and (3) in effecting this with as little resistance as possible to the flow Accuracy in oxygen supply is another step towards perfection for a minimum of 0 c cm of oxygen per breath will make an enormous difference in the composition of the respired gases For this purpose I have had constructed a special flowmeter for small flows of from 250 c cm oxygen upward

Briefly the principle is a well known one of the absorption of the patient's carbon dioxide by soda lime The patient rebreathes the same amount of nitrous oxide continuously as this is given out from the lungs unchanged Oxygen is used constantly of course and it is necessary to give correctly graded quantities of this latter gas continually Either when employed can be added to replace what has been used up By this method one consumes an extremely small quantity of gas One or two gallons per hour is the usual amount as opposed to 100 to 150 gallons per hour—a great saving

APPARATUS

This consists of a circular rebreather as compared with the ordinary single tube to and fro method In the face piece mount are two very fine flap valves made from thin Paul's tubing These valves are the most important



[illegible] of the [illegible] both [illegible]

part of the apparatus as they regulate the flow of the [illegible] unidirectional [illegible] impeded In the [illegible] tubes run to a [illegible] absorber The [illegible] and holds a [illegible] position by two [illegible] and cork The [illegible] full of [illegible] the [illegible] quantity [illegible] of oxygen [illegible]

oxygen etc Ether is admitted to the apparatus in one of two ways—by a Clover inhaler or by the oxygen tube from a Boyle's machine

Position of Administration

The anæsthetist is supported by clips to the Boyle machine *between the face piece and* The patient is induced with gas and oxygen till conditions is right Then a Clover inhaler is fixed over the face to ensure a perfect fit of the face piece this is most important The expiratory valve is now closed down tightly and the gas flow stopped The oxygen supply is reduced to 00 to 200 c.c. per minute Ether is now added from the Clover if this instrument is being used or by the oxygen tube allowed to bubble through the ether in the Boyle's machine

In practice it is found that one minute's oxygen always has to be given so that a few cubic centimetres are added from time to time to keep the bag full but actually only one to two gallons are needed per hour One cannot use this method on laughing gas as gas always leaks away a little and it has been shown that nitrous oxide is excreted by the skin in small amounts One charge of soda lime lasts for six to eight anæsthetic hours and all the apparatus can be sterilized by boiling The flutter valves are easily replaced, and give no trouble No provision has been made for switching out the absorber from the circuit It is so easy to plug the bag directly on to the Y piece that it was felt advisable to avoid further sources of possible leaks In practice it is found that the respiration rate with the absorber in use is quite unchanged its depth too being almost unaltered and not nearly as great as that obtained with a Clover's ether inhaler or similar closed method of anæsthesia

Conclusions

The method has no disadvantages Its advantages which are many are as follows

1 To the patient (*a*) No loss of heat through the lung and therefore (*b*) less risk of bronchitis etc (*c*) Minimal use of ether

2 To the anæsthetist (*a*) No smell of anæsthetic in the theatre (*b*) Economy in gas and ether (*c*) Extreme portability—twenty five gallon cylinders need only be carried instead of hundred gallon ones—a great saving in weight

The apparatus was made for me by A Charles King Ltd, Devonshire Street W 1

THE USE OF TAKAYAMA'S SOLUTION IN THE IDENTIFICATION OF BLOOD STAINS*

Though the importance of the production and identification of crystals derived from blood in medico legal cases has received much emphasis in the literature little change has occurred in recent years in the methods employed for their demonstration

History of Tests

Teichmann in 1853 noted the appearance of brownish rhombic crystals when blood was treated with glacial acetic acid and a trace of sodium chloride These crystals were later identified as being those of hæmatin chloride and since then it has been recognized universally that their presence is proof of the identity of the suspected stain with blood Unfortunately it was soon found that such crystals could only be demonstrated with difficulty and uncertainty Many attempts to modify the technique and to simplify the procedure were made but few of these modifications had much to offer Probably the best was devised by Sutherland[1] who suggested that a small drop of normal saline should be evaporated to dryness on a slide before the fragments of the suspected stain were deposited on it glacial acetic acid was then added and the slide heated gently Even this method frequently fails of its object Later Donoghue and Bürker[2] suggested the use of pyridine for demonstrating hæmochromogen crystals in blood Pyridine used alone however gave rather uncertain results and attempts were made to devise a solution containing this reagent which would be more successful Takayama[3] in 1912 suggested a solution of the following composition

Pyridine	3 ml
Sodium hydrate 10 per cent solution	5 ml
Dextrose sat solution	7 ml
Distilled water	7 ml

Mahler[4] in 1923 and Kerr and Mason[5] in 1926 reported favourable results with this solution and since this time it has found mention in a hesitating way in some of the textbooks though it has obviously not attained the recognition to which its usefulness entitles it It has given unfailing satisfaction in my own hands and I feel that it deserves to be incorporated more widely into routine usage Sutherland in a textbook article on blood stains describes his own routine method of examination of suspected stains as follows He removes a tiny fragment of the material containing the stain plunges it into boiling water for a few seconds transfers it to a slide and removes the water by blotting A drop or two of 10 per cent KCN solution is now added and the slide again blotted finally a drop of strong ammonium sulphide solution is placed on the fragment a cover slip adjusted and the preparation examined microscopically If blood is present a salmon pink colour will be seen and microspectroscopic examination will show the spectrum of hæmochromogen He feels that no further proof of the presence of blood is required

Technique of Method

The method of using Takayama's solution to be described accomplishes all that Sutherland's method does but in addition demonstrates hæmochromogen crystals

* From the Bacteriological Institute Medical Department Hong Kong (Hon Dr A R Wellington Director of Medical and Sanitary Services)

and does so with simplicity and certainty I have never failed to obtain crystals in a known positive case Occasionally an old stain may require a little longer treatment but the result seems to follow just as surely It must be emphasized that the reagent should be freshly prepared if prompt reaction is expected It gives satisfactory results for about two months only although I have obtained crystals using a solution six months old

The method is as follows With a sharp scalpel a portion of the suspected stain is scraped off the weapon or other article on to a clean slide *The smaller the fragment the better* The largest portion on the slide should not exceed about half the size of an ordinary pin's head I find that the minute scraping which sometimes adheres to the scalpel usually suffices this often has to be removed with another scalpel or some instrument possessing an edge Taking care that this is not blown off the slide a drop of Takayama's solution is placed on it and a cover slip adjusted It is important that the drop be not too large otherwise the cover slip will float on the surface and the formation of crystals will be delayed In the case of a stain on fabric a good method of procedure is to cut out the stained portion and having placed it on the centre of a slide to scrape gently the surface of the stain with a sharp scalpel until a few minute fragments of fluff are deposited on the slide a drop of the solution is then added as before It is necessary that the laboratory bench be free from air draughts lest the material on the slide be blown away before the solution is added On microscopical examination (which should be immediate) if the blood is present a distinct pinkish area will very soon be seen among the debris on the slide As soon as this is identified the ocular of the microscope should be removed and the tube of a hand spectroscope with a wave length scale inserted in its place The characteristic bands of haemochromogen should be made out and the reading of the scale taken Emphasis is laid on the necessity for immediate examination as I have found that the spectrum is much more distinct and more surely obtained before crystal formation than after Usually if the blood stain is reasonably fresh crystals will form in from two to five minutes but it is well to leave a slide for re-examination some hours later before recording a negative

The crystals are so characteristic in colour and shape that they cannot be mistaken by an observer with even a little experience They are of a pink to salmon pink colour and in shape are flat and rhomboid The ends of individual crystals are often splintered Some crystals terminate in a blunt point like the blade of a pocket-knife others again are quite rectangular Seen on edge they are like sharp lines There is a strong tendency to sheaf formation The best crystals are the rather fine separate ones seen off the edge of the fragment actually in the solution against a clear background These take longer to form and are rather small but are well worth study under the oil immersion lens Another characteristic type of crystal which I have seen occasionally is derived from fairly fresh blood stains The crystals are curved instead of flat and tend to lie so as to present their thin surfaces uppermost the result being a number of fine curved dark pink lines giving a most striking appearance to the microscopical field Such crystals as do not lie completely on their sides may be seen to present the same rectangular structure and there are practically always plenty of the more usual flat forms to be seen as well

The colour change described by Kerr and Mason after the addition of Takayama's solution—namely green brown dark red to pink—has not been observed certainly by myself but this does not seem of great importance I have found the use of heat entirely unnecessary where delay occurs in crystal formation I merely leave the preparation at room temperature for fifteen minutes to half an hour examining it at intervals Should the material for study be scanty and crystals few and possibly very fine necessitating the use of a high magnification care should be taken to focus down very slowly and cautiously to watch for fine crystals on the surface of the preparation Often this is the first place at which crystal formation occurs and they may be picked up at this point many minutes before being seen at any other level in cases of difficulty It is unfortunately very easy to focus past the surface and miss these crystals Where they are slow in appearing I have found that they may at times be caused to appear by gently tapping the microscope stage

GENERAL CONSIDERATIONS

Carried out in this manner we thus have a perfectly definite diagnostic triad a colour reaction the formation of specific crystals and the production of certain bands at specific points in the spectrum No other known substance but blood will give these three reactions in the circumstances described If a positive result has been obtained in this manner no further test is necessary in order that testimony may be borne as to the presence of blood In fact it is bad practice to use other tests the results of which may possibly be negative in the presence of blood and whose positivity does not alone justify one in affirming that the stain is of blood Should such tests be negative or doubtful the positive evidence already obtained is immediately weakened in the eyes of a jury Logically speaking a test the results of which are open to criticism cannot strengthen the results of one possessing an absolute value It is good practice however if sufficient material is available to obtain a solution of the stain and to demonstrate if possible the spectrum of oxy or methaemoglobin macroscopically and then by treatment with caustic soda and ammonium sulphide solution obtain the spectrum of haemochromogen This too is also an absolute test for blood Unhappily the material available is all too frequently insufficient for this procedure and it is in such cases especially that the procedure described is invaluable

No claim to originality in the use of the method is intended but it is felt that a description of a good routine application of Takayama's solution is needed and that some such method deserves far wider usage than it appears to have at the present moment among those practising forensic medicine

TWO FURTHER CASES OF SARCOMA ASSOCIATED WITH KNOWN TRAUMA

BY

DAVID H HALER

PATHOLOGIST INFANTS HOSPITAL S W LATELY ASSISTANT PATHOLOGIST PRINCE OF WALES'S HOSPITAL W

In a recent article in the *British Medical Journal* I was able to record two cases of sarcoma in association with known trauma In the following note I propose to describe two similar cases wherein two totally different organs were involved

CASE I

In the first case the patient a boy of 17 was playing with his dog in the garden when he received a blow on the right testicle This was attended with marked pain and rapid swelling which was treated as a traumatic haematocele As

the swelling did not subside he attended the out patient department and the swelling was tapped yielding a few ounces of obviously altered blood In spite of treatment the swelling continued to get larger at a rather more rapid rate The following fortnight the patient commenced to feel unwell remained in bed his appetite failed and he experienced later more than usual pain

Physical examination revealed a well nourished youth with a large right chest cystic swelling which was somewhat opaque to transillumination only lightly tender and thumb punctured On pressure the swelling was progressively diagnosed as a haematoma and operation performed through a right mammal incision when a large tumour of the mammary gland was expected This was removed a fortnight after the original injury

A curious late result of the operation the general health of the patient was somewhat good until eighteen days later when acute facial dyspnœa occurred The patient died in spite of treatment Although there was rapid healing of local wounds post mortem examination revealed no evidence of pelvic secondary deposit or pulmonary and pleural involvement He had therefore survived operation approximately seven months after original accident

Post mortem Examination—Extensive emaciation There was a large healed incised wound left inguinal area and scrotum and penis and testis The testis was in the abdominal cavity and the cardiac cysts lymph nodes and other abdominal viscera were normal

There was a pathological fracture of right humerus with a large soft tissue callus and fracture of left humerus with callus Both lungs were studded with primary and plaque like secondary growths all over the pleural surfaces and numerous intrapulmonary deposits The original growths involved the cutis and subcutaneous tissue of the original wound

Several blood clots were present in the cord of the left ventricle and there were numerous pulmonary and pleural secondaries

Microscopically abundant metastatic deposits chiefly in the lungs which infiltrate the entire chain

Section of primary and secondary growth showed a typical round and spindle celled sarcoma with extremely active mitosis

Case II

In July 1931 a Sealyham bitch aged 12 was chasing a cat in the garden when she tripped herself on one left breast She wounded herself and was dressed by the owner with a boracic dressing The lesion healed by secondary intention leaving rather a puckered scar At the time of the original injury there was a good deal of bruising seen and the swelling associated with this never subsided The case was first seen by a veterinary surgeon in September 1931 when he found an enormous mammary growth showing at its most prominent part a recently healed puckered scar The tumour was excised under general anæsthesia and the wound healed briskly by first intention

In December 1931 a swelling began to appear from under the ribs the dog went off her food and the swelling continued to increase in size This was shown later to be a large secondary hepatic deposit The animal died from asthenia and secondary liver growths in January 1932 There was no post mortem

Examination of Specimen—Large nodular encapsulated tumour of left mammary region—weight 2 lb (total weight of the animal 12 lb) The tumour bears on the cutaneous surface a stretched fibrous scar the area of skin surrounding this is depressed and sections taken at this point show a dense belt of fibrous tissue separating skin from tumour which elsewhere pushes up immediately beneath the skin Large areas of the tumour show yellow or haemorrhagic degeneration with some hyaline colliquative necrosis and cystic degeneration

Microscopical appearances In one area there is considerable epithelial hyperplasia elsewhere the skin is thinned and atrophic The cutaneous appendages extend well into the scar tissue Some dilated epithelial lined spaces are seen these are possibly of sweat gland origin The tumour itself is composed of spindle cell sometimes closely packed sometimes oedematous and interspaced with inflammatory cells There is a certain amount of variation in cell size and form Large vascular spaces many formed of tumour cells are present Much hyaline degeneration is also seen The tumour is a fairly malignant spindle celled sarcoma

The cases both of which have been confirmed by careful microscopical examination are interesting from the point of view of the association of sarcoma and known trauma

I am indebted to Mr Dickson Wright for permission to publish Case I I should also like to express my thanks to Mr C H Bryans M R C V S of Bournemouth who so kindly provided the history in Case II as well as the pathological material

AMBULATORY TREATMENT OF VARICOSE VEINS BY COMBINATION OF LIGATION AND INJECTION

BY

A DICKSON WRIGHT M S F R C S

SENIOR ASSISTANT SURGEON TO OUT PATIENTS ST MARY'S HOSPITAL AND SENIOR SURGEON FRENCH OF WALES HOSPITAL

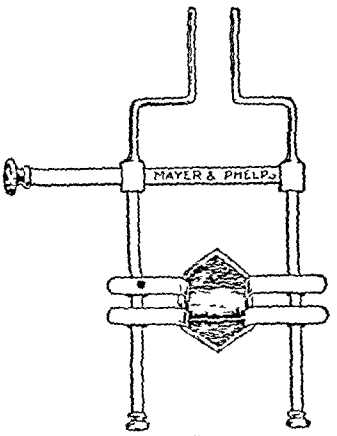
Some disappointment is caused in certain cases of very extensive varicose veins by the difficulty experienced in inducing large veins to react to the various sclerosing solutions It has been suggested that in these cases two solutions should be injected more or less simultaneously so as to produce a precipitate of insoluble quinine salicylate crystals in the interior of the vein I have always felt this to be a very dangerous procedure for obvious reasons Further it is fairly certain that a considerable number of these large veins will recanalize after a time even when they have been coaxed into thrombosing Maingot has recently said that 30 per cent recanalize with sodium morrhuate injections and Howard Jackson and Mahon have found 9% per cent to recanalize after sodium chloride injections in a careful analysis of forty eight cases followed for a year or more

Technique of Method

Feeling that the solution of both problems lies in a combination of ligation and injection I have used the simple technique here described for the ligation of varicose veins as part of the ambulatory treatment The vein selected for ligation is the parent vein of a group of veins and the most prominent rather than the highest portion of it is selected for ligation

The skin is sterilized and anaesthetized with novocain solution An incision half an inch long is then made *across* the line of the vein and when the subcutaneous tissue is reached the small retractor shown in Fig 1 is inserted (This instrument is an adaptation of Irwin Moore's beautifully designed laryngo fissure retractor) The vein is then picked up and freed from connective tissue the retractor removed and turned round and the prongs inserted under the vein and separated Owing to the self retaining nature of the retractor the vein is thus kept on the stretch and elevated out of the wound (Fig 2) While so held 2 c.cm of 5 per cent sodium morrhuate are injected into the lumen of the vein The object of this injection is to fix the thrombus which will form after the ligation above and below the ligature Two ligatures of catgut are now passed round the vein at least an inch apart and the vein divided between them

(Fig 2 A) Should the portion of vein selected have any tributaries they should be ligated as a preliminary to tying the main vein It is essential that the vein should be tied cleanly without the inclusion of any connective tissue and attention to this with the large stumps beyond the ligatures precludes any chance of a ligature slipping The wound can be closed with fine silkworm gut passed through hypodermic needles (Fig 2 B) so as to reduce the number of instruments required The retractor and vein stretcher has been made for me by Messrs Mayer and Phelps and I have found it useful in other minor operative



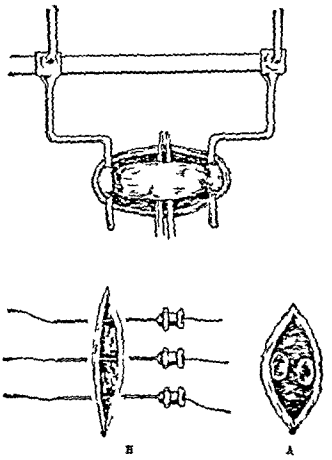


FIG 1

B A

FIG 2

procedures usually performed single handed where the main difficulties are to keep the wound open and to check oozing These are overcome by this small instrument

Specific Advantages

The advantage of this procedure over injection alone is that it hastens the treatment because a much smaller number of injections are needed to produce results Such an advantage is too obvious to stress It is moreover absolutely certain to produce results whereas injection alone often disappoints The veins below the ligature collapse so that bulky clots do not form there is less pain and the induration of the vein resolves more quickly Lastly the method gives a greater guarantee against recurrences than injection alone I have now treated over one hundred cases by this method without complication of any kind and I have come to regard it as a very valuable adjunct to injection treatment of varicose veins of certain types Moreover it seems to be perfectly safe and does not necessitate the patient lying up or abstaining from work The results are so good that I am surprised multiple ligation was not the method of choice in pre injection days instead of the rather ruthless and unsurgical procedures often employed in the past with results which did far from justification to them

The following illustrates well the type of case which benefits most from this treatment

CASE RECORD

Miss J had had repeated attacks of ulceration for the last ten years She was of stout build Both legs showed the scars of ulceration and there were extremely bulky and extensive varicose veins from the groins to the feet The ulcers had always healed as a result of long rests in bed Most of the doctors she had consulted previously had held the veins to be too hopelessly diseased to make a cure by injection worth attempting One doctor had made a series of seven injections in one leg from one of which she developed a necrosis but from none of them did any thrombosis result On account of this history and the extent of the veins I regarded her as a case best treated by a combination of injection and ligature With the right leg I performed three ligation injections and three simple injections and secured a complete and uniform thrombosis of all the veins without any severe reaction On the left leg two ligation injections and three simple injections sufficed to effect a very satisfactory cure I feel sure that with injection alone the treatment would have been very tedious—possibly rather painful—and in this type of case the veins would be likely to recur

I wish to thank Messrs Mayer and Phelps for supplying the blocks

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

BASOPHILIC HYPERPITUITARISM (CUSHING'S ENDOCRINE PITUITARY SYNDROME) AND ? BASOPHILIC HYPOPITUITARISM

If Professor Harvey Cushing is right in his suggestion that the remarkable syndrome which he has recently discussed (*Johns Hopkins Hosp Bull* 1932 l 137) is due to the presence of a basophil adenoma in the anterior lobe of the pituitary body and for which he has suggested the term pituitary basophilism it might well for convenience be referred to as Cushing's syndrome at all events till more is known on the subject My own case of Cushing's syndrome I described (*Brit Journ Dermatol and Syph* 1926 xxxviii 1) under the cumbersome heading of Cutaneous striae purpura high blood pressure amenorrhœa and obesity and to complete the clinical title I might have added with severe trophic changes in the skin of the legs Incidentally I should like to correct a slight error in Professor Cushing's careful reference to the case The minute basophilic adenoma in the anterior lobe of the pituitary body was discovered by Dr E Bock (a pupil of Professor Aschoff) who was at that time working as pathologist at the German Hospital This was almost the first case of the kind in which a pituitary basophilic adenoma was definitely stated to have been present I afterwards lent the paraffin block and a photomicrograph of an admirable section made by Professor H M Turnbull was sent to Professor Cushing whence that slight error

Of the various case collected by Professor Cushny, he own patient died in 1912 still living and I may add that every typical example in a young woman aged 18 years who had character ic cutaneous changes was seen by us with Dr Adolphe Abrahams in 1925 and so far as I know getting on fairly well in the circumstances with high blood pressure and haematuria. The high blood pressure and the renal changes are of the greatest interest and suggest that a pituitary basophilic adenoma like tumour is extremely rare primary endocrine tumour of the chromaffine cells of the suprarenal medulla may be an exceptional cause of persistent high blood pressure and of arterial sclerotic changes.

In the future of Cushing syndrome will doubtless become more frequently recognized from time to time but their early recognition will be difficult and doubtful. If Cushing syndrome is really due to basophilic hyperpituitarism which I consider a convenient term to distinguish it from acidophil hyperpituitarism—the cause of eosinophilic adenoma, the basophil—it may be expected that basophil hyperpituitarism never occurs without changes in the basophil cells of other endocrine glands. In the common I cannot help thinking of the small basophil prostate was particularly abundant in the hypertrophied part of the body but I have never had a chance to examine the prostate in Cushing syndrome though the less may I have to add that in this I should much welcome information.

One is very much struck by a temporary basophilic hyperpituitarism as a part factor in connexion with a high adrenalin strain atrophy of adrenal cortex and true cortical with typhoid fever and other infections.

The case of suprarenal tumour is not necessarily malignant to adrenal endocrine activity and this should be borne in mind in regard to the possible effects of basophil and of eosinophil adenomata. Similarly the cases with thyrotoxic symptoms in Graves's disease are not necessarily due with the large goitres. In this connexion may also note that in myeloid and lymphatic leukaemia the bone marrow may be full of immature white cells even though the circulating blood shows an absolute leucopenia.

I. PARKES WEBER, M.D., F.R.C.P.
Senior Physician to the German Hospital, London.

CASE OF SUSPECTED RAT BITE FEVER

The following are some notes of a rather unusual type of infectious disease recently seen at Cumnock, Ayrshire.

On July 29th 1941 the patient aged 10 was playing in the burgh rabbit hutch when he was bitten by a rat on the dorsum of the right big toe. The rat appeared to be in poor condition for it was caught by the boy and swung round by the tail before biting him. The wound was dressed and iodine applied. Healing took place in the usual way and was not characterized by any unusual feature.

The boy was first seen by the family doctor on August 21st when he complained of severe headache and general malaise of four days' duration. The temperature was 104.5° F. and the pulse relatively slow, 100. (This was noticeable in all the subsequent attacks.) There was some tenderness on pressure in the right iliac fossa; enlargement of the inguinal gland would probably account for this. The urine showed a trace quantity of albumin but no casts. At this stage the possibility of typhoid fever was considered. The Widal test however was negative. There was on this occasion a small patch of erythema at the root of the nose. This was ascribed to a bite. It reappeared in subsequent attacks. The boy's temperature came down by lysis in four days, and on August 27th he was able to get up.

On September 3rd he had a recurrence. His face was swollen and he complained of pain in the calves. There was some redness of the fauces with hoarseness of the voice and this occurred in subsequent attacks. The glands in the posterior triangle of the neck were enlarged and tender as were also those in the axilla and groin. No palpable splenic enlargement was noted. On this occasion the temperature came down by crisis in twenty-four hours to 99° F. At this time the possibility of rat bite fever was not entertained as a history was obtained of the rat bite.

On September 11th a further recurrence took place. A rash now appeared on the face, abdomen, and buttocks. This was in the form of small rings with a raised, red, erythematous outline and a pale smooth centre. The temperature again came down by crisis and the rash rapidly faded.

On September 16th he had another recurrence, the temperature being 105° F. The erythematous patches were more numerous and defined, more numerous than formerly. At this juncture the history of the rat bite was obtained and the condition was diagnosed. The glands were again enlarged and tender. He had subsequent attacks every four to five days with each onset temperature 104° to 105° F. and coming down by crisis in eighteen to twenty-four hours. He remained well between the attacks.

The week after this attack he was given stabilarsan 0.1 gram, followed at intervals of a week by further doses of 0.15 and 0.2 gram. It was thought this dosage should be sufficient to stop the attacks entirely, but a further recurrence necessitated a larger dose of 0.4. No further attacks took place.

He was later admitted to the Victoria Infirmary, Glasgow, and was under the charge of Dr. Douglas Russell. His temperature however remained normal and no rash developed, although he had no further treatment. He is now well and at home.

Blood films taken during the attacks showed no abnormality apart from some leucocytosis. A sample of blood was also injected into a guinea-pig without any result.

I am indebted to Drs. McQueen Armitage and Hay of Cumnock for bringing this case to my notice, also for the clinical details.

PETER HUTCHISON, M.B., Ch.B., D.P.H.
Senior Assistant M.O.H., County of Ayr.

Reports of Societies

DIAGNOSIS OF PREGNANCY

At a meeting of the London Association of the Medical Women's Federation held on April 26th with Dr. LETITIA FAIRFIELD in the chair, Lady BARRETT proposed that a group should be formed for the study of anaesthesia in midwifery, the group to be composed of women obstetricians and gynaecologists in London. This proposal was accepted.

Dr. CLAUDIA DODDS then delivered an address on the Zondek-Aschheim test. Tests for pregnancy used in the past, she said, had shown a large percentage of error, but the accuracy of the Zondek-Aschheim test had been confirmed by everyone who had used it. During pregnancy the urine contained oestrin and a hormone secreted by the anterior lobe of the pituitary. It was upon the anterior lobe hormone that the test depended; this stimulated the development of ovarian follicles and ovulation, as a result of which oestrin was secreted. It was non-specific, inducing changes in the ovary of the female and in the testis of the male; oestrin however was a specifically female hormone. When the urine of a pregnant woman was injected into immature mice it produced ovarian changes which could be used for the diagnosis of pregnancy. The exact day on which the anterior lobe hormone first appeared in the urine of a pregnant woman had not been ascertained. It was present by the third day after the first missed menstrual period, and it was thought to appear after embedding of the ovum. The

amount of hormone secreted in the urine increased rapidly and reached a maximum during the first two months of pregnancy it disappeared on about the eighth day of the puerperium The oestrin in the urine increased more slowly and reached a maximum between the third and seventh months it also disappeared on about the eighth day of the puerperium Five immature female mice each weighing 6 to 8 grams were used in making the diagnosis and received injections of 5 c cm of urine over a period of three days they were killed 100 hours later and the ovaries examined If the result was positive the following changes would be found (1) The ovaries might be enlarged and pinkish with enlarged follicles visible macroscopically and microscopically These changes were not diagnostic of pregnancy they might follow the injection of urine from patients suffering from carcinoma endocrine disturbances such as hypothyroidism from the menopause or from patients who had been castrated (2) One or more blood points might be seen on the ovary and on microscopical examination massive bleeding into the follicles would be found (3) Corpora lutea might be present The second and third changes were diagnostic of pregnancy The test was valuable in distinguishing the amenorrhoea of pregnancy from amenorrhoea due to other causes Fibroids complicating pregnancy sometimes led to difficulties of diagnosis In pulmonary tuberculosis heart disease or chronic nephritis the test was particularly useful in establishing the early diagnosis of pregnancy it could also be used in making the differential diagnosis between ectopic gestation and acute salpingitis or adnexal tumour A positive result was not proof of a living pregnancy but only of living placental tissue In the presence of hydatidiform mole and chorion epithelioma the test was often positive with unusually high dilutions of urine The greater the dilution the greater was the suspicion of some abnormality of the placental tissue If the test had become negative following delivery and subsequently became positive again there was a strong suspicion that chorion epithelioma was present She described a case of this kind in which panhysterectomy had been performed the Zondek Aschheim test had again become negative following the operation and had remained negative ever since There had been no sign of recurrence

Dr DULCIE STAVELEY then spoke on the diagnosis of pregnancy by *x* rays The fact of pregnancy she said was usually established before *x* rays were used For diagnostic purposes radiography had little value before about the sixteenth week though in the United States it was claimed that a diagnosis could be made at the fourteenth week Usually a ray examination was used to confirm the diagnosis A method of injecting lipiodol into the uterus in order to make an earlier diagnosis was said not to cause abortion but it only showed a rounded swelling in the wall of the uterus which was not in itself diagnostic of pregnancy Adiposity of the patient might help to obscure the picture and a lively baby sometimes spoiled the film by moving The spine was the first part of the foetus to become visible upon *x* ray examination and showed first as a row of stippled dots patches of calcification in a fibroid might be confused with the early appearance of the spine The maturity of the foetus could be estimated by the size of the spine and skull and by the appearance of the various bones in the skiagram The os calcis appeared between the twenty-first and the twenty ninth week the astragalus between the twenty fourth and the thirty second week and the epiphysis of the femur at about the thirty sixth week In a post mature foetus the epiphysis of the upper end of the tibia might be seen Estimation of maturity however could not be made more accurately than within a fortnight X ray investigation was valuable in clearing up the diagnosis in suspected multiple pregnancy A dead foetus could often be recognized by a sagging attitude overlapping of the cranial bones and by the fact that no growth was seen to have taken place when a second examination was made after an interval Often too the foetus would be found to be in exactly the same position at the second examination as at the first Malpresentations—such as breech with extended legs face and transverse presentations—could be demonstrated by radiography The placenta was not normally visible but it might show calcified patches which might be useful in the diagnosis of placenta praevia Abnormalities in the mother such as lordosis scoliosis spondylitis osteomalacia or deformities of the pelvis or hip joint could be demonstrated Disproportion between the head and the pelvis could not be demonstrated well by a lateral view but recently it had been made possible to take a vertical radiograph showing the fit of the head in the pelvis and measurements could be made against a calibrated scale Abnormalities of the foetus such as anencephaly hydrocephaly and even spina bifida might be demonstrated radiographically before birth Dr Staveley showed lantern slides of radiograms of the conditions described

TWO PAPERS ON MALIGNANT DISEASE

At a meeting of the Manchester Medical Society held on April 6th papers were read by Dr R Ralston Paterson and Professor S L Baker on The radio sensitivity of tumours and The virus theory of cancer respectively

Radio sensitivity

Dr PATERSON said that tissues varied markedly in their response to radiation—*x* rays and *γ* rays The property of tissue which underlay this variable response was called radio sensitivity or at the other end of the scale radio resistance In particular tumours showed a wide range of such sensitivity By contrasting the sensitivity of growths with the sensitivity of the skin—in both cases using the minimum lethal dose as the standard—it was possible to place tumours in four groups—radio sensitive tumours epitheliomata adenocarcinomata and radio resistant tumours The first group comprised pathologically a heterogeneous number of growths though clinically it included many highly malignant growths which metastasized early The lethal dose for this group of tumours was less than the lethal dose for the skin and thus sufficient radiation to produce lethal changes could be given by external methods of radiation alone External methods of irradiation *x* rays in larger tumours external radium in more localized tumours thus became the treatment of choice

In epitheliomata were included also the epithelial tumours of the breast excepting true adenocarcinoma because whatever their nature they acted from the point of view of their reaction to radiation as did the squamous epitheliomata This group included a high percentage of the malignant tumours and was therefore correspondingly important To produce lethal changes in those growths a quantity of irradiation must be used which was approximately in the region of the lethal dose for skin They did not therefore lend themselves to satisfactory curative treatment by external methods of irradiation alone and had in practice to be treated if by irradiation at all by localized irradiation which could only be achieved by means of radium The treatment of choice must therefore always lie between such localized irradiation methods and surgery This choice was made by a contrast of the ease or difficulty of technical procedures involved of functional results or of probable survival by one or other method

In the third group adenocarcinomata, growths appeared to require a lethal dose greater than the skin lethal dose and normally equal to the lethal dose for the tumour bed. Irradiation whether external or localized could therefore only act as a general cautery. In view of the fact that there were many safer and less expensive cauteries irradiation seemed contraindicated and the treatment of choice in this group was always surgery.

Radio-resistant tumours were heterogeneous pathologically but for the most part of connective tissue origin. Like normal connective tissue they were highly radio-resistant and it would appear that the lethal dose for them was not only greater than the lethal dose for the skin but even greater than the lethal dose for the normal tissues in which these *tumours tended to grow*. The use of irradiation to effect direct curative action appeared more likely to do damage to the normal than to the abnormal tissue and was thus definitely contraindicated. In this group however should surgical extirpation be impossible another process became available—that called by Ewing growth restraint. Here repeated small doses of irradiation were used to produce an effect on the endothelial lining of the vascular system of the tumours a process resembling endarteritis obliterans ensued with resulting cessation of or marked slowing of growth. These four groups covered the whole field of tumours and gave an indication as to the choice of treatment once one knew to which group any particular tumour belonged. In this field of radiotherapy there were two likely fields for research work in the future. In the pathological field there was the problem of ascertaining the exact criteria underlying the relationship between pathological types and radio-sensitivity. In the experimental field attempts were being made to increase radio-sensitivity either by alterations in the time factor of treatment or by intravenous method. Could such increased radio-sensitivity be produced tumour would then be rendered more amenable to irradiation therapy.

The Virus Theory

Prof. G. BARRY said that although many and various predisposing causes of cancer were known the fundamental cause of the abnormal cell proliferation which was the central fact of cancer could be narrowed down to two possibilities. (1) The biological or mutation theory which postulated an alteration or mutation of the cell initiated by some chemical or physical stimulus. This change once initiated was handed on to subsequent generations of cells by the ordinary laws of cell inheritance the inheritance of an acquired character. (2) The virus theory which postulated a continuously acting cause an infection of the cell by an agent which multiplied and was thus carried on through successive generations of cells.

In the case of mammalian tumours there was a great weight of both histological and experimental evidence in support of the cell as the cancer unit. Cancer in mammals could only be transmitted experimentally by grafting living tumour cells to new hosts of the same species. No cancer-causing agent had ever been separated from the cells of mammalian tumours. There was no experimental evidence that suggested that a living virus could be responsible for the production of a tumour until in 1911 Peyton Rous published his first account of a fowl sarcoma transmissible experimentally from bird to bird by a filterable agent separable from the tumour cells. It was now known that many different types of sarcoma in the fowl could be transmitted in this manner. The fowl sarcomata apart from this peculiar property of filterability differed in no way from mammalian sarcomata. The tumours occurred sporadically and there was no evidence of infectivity under natural conditions. The tumour was essentially a local lesion and there was considerable evidence to show that metastases were produced by detached cell fragments as with mammalian tumours and not by the dissemination of the infective agent about the body. A strain of fowl sarcoma was not always filterable and often passed through stages where it could only be transmitted by cell suspensions. Carcinomas occurred in fowls but a transplantable strain had never been established and their filterability had therefore not been studied. The exact bearing of these fowl tumours upon mammalian cancer remained at the present time a matter of conjecture but the facts so far obtained were so peculiar and striking that a continued investigation of them was clearly indicated.

"EXCESSIVE SURGERY"

A meeting of the West London Medico-Chirurgical Society was held on May 4th with Dr. H. H. MILLS in the chair when the subject for discussion was "Excessive Surgery."

Mr. HAMBLEN THOMAS gave a brief sketch of the history of surgery, pointing out how at various times the physician and the surgeon had eclipsed one another. Most surgical treatment of disease to-day, apart from repair or correction of deformity, consisted in removal with a varying amount of mutilation and there was always a certain amount of risk to the patient's life. Occasionally one wondered whether operation need be so extensive as in the removal of the breast for carcinoma where the results of simple amputation were as good as those of the extensive Halstead operation. A cerebral decompression was often attended with better results than say an extensive resection of the colon for toxæmia—to take an instance of drastic surgery. Occasionally surgery was misdirected as when tonsils were removed in cases where their disease was secondary to overlooked nasal trouble.

Dr. GEOFFREY EVANS said that as a physician he was rather conscious that pain was from time to time the cause of excessive surgery. A number of patients were operated on unnecessarily for functional abdominal pain—spastic colon and the like. With regard to gastric ulcer one had to recognize the fact that medical treatment was very successful in this condition and surgery also. He believed that if one was afraid of death from haemorrhage or feared perforation one should get the surgeon to operate but if that fear did not obtain the patient should be allowed to go on for two or three years with medical treatment an operation only taking place if that was unsuccessful. In this territory where physicians and surgeons were watching each other frank collaboration as carried out at present in London was obviously the ideal. The moral of his remarks was that surgery was not at present excessive but he rather feared that it might become so.

Mr. ZACHARY COPE discussed the factors which had to be considered before deciding to operate. With regard to the patient himself he expressed the view that it was no part of the surgeon's duty to say to the patient "If you do not have this done you will die." He had known patients recover after that had been said. If a patient was over-persuaded into an operation the surgeon had gone half-way towards failure at the start. Again no operation ought to be done before a routine examination had been made. The man who was quite sure of his diagnosis before he examined was often wrong. The next thing to remember was not to operate merely because the patient had something which was abnormal. For example every man over 50 or 60 probably had some enlargement of the prostate but this in itself was no ground for operation unless it gave rise to symptoms. Further, one

ought not to operate in any condition which was amenable to medical treatment until such treatment had been thoroughly tried The economic condition of the patient had a bearing here In the case of duodenal ulcer for example patients in poor circumstances might be relieved from time to time by medical treatment and have to lay up again and these frequent illnesses might ultimately have the result of causing them to lose their job In these cases one should operate sooner for gastric or duodenal ulcer than one would in persons belonging to a class which could afford to be cured several times before going to the surgeon There was also a time in the history of each disease which was the best time to operate It was worse than unwise to operate at an unpropitious moment The surroundings of the patient had to be considered and in most cases the hospital or nursing home gave the patient a much better chance of recovery than did his own domicile Another point to remember was that although every qualified man was justified in law in undertaking any operation every surgeon knew that he had his limitations and the specialist limited himself to those diseases for dealing with which he had a special aptitude It was for every surgeon and every practitioner to consider whether there were not limitations to the range of his capabilities

Mr SAINGSTER SIMMONDS classified physicians and surgeons under four heads the ultra medical physician who kept the patient with pyloric stenosis from the surgeon until he was moribund the equally excessive surgical surgeon who would do a thyroidectomy for every case of goitre the surgically minded physician who would treat a gastric ulcer medically and give it a thorough chance and only if he failed hand it over to the surgeon and the medically minded surgeon who if he had a gastric ulcer himself would have it treated medically for a long time before he had it treated surgically One reason why surgery was being overdone was because the training of the surgeon was so encircled The whole hospital system of London gave rise to such watertight compartments that very few surgeons had any training in general practice He learned that in Spain it was the custom if the doctor said that there should be an operation for another consultant to be called in and only if the two agreed together was the operation consented to

Dr MAURICE SHAW said that there were quite a number of cases in which one was bound to do a laparotomy and nothing was discovered These operations might be classed as excessive surgery but he scarcely thought that such a definition would be justifiable The surgeon had the right to complain that sometimes the physician did not send him his cases early enough sending them only after medical treatment had failed He thought that surgery after all as the Greek word from which chirurgery was derived signified was a handicraft and while he did not object to the surgeon being a diagnostician what he would most like to see was physicians absolutely competent in the diagnosis of all complaints and surgeons competent in performing operations in their own particular branch Mr F McG LOUGHNANE could not agree that there was excessive surgery his belief was that there was not enough surgery being done at the present moment If only certain conditions were operated upon earlier many maladies would be prevented He contested in particular Mr Cope's remark that mere enlargement of the prostate was not a sufficient reason for operation If an enlarged prostate which gave no symptoms was investigated by the cystoscope and the urethroscope it would show signs of becoming damaged The PRESIDENT (Dr Mills) expressed his belief that if infants and young children were more thoroughly examined from the preventive point of view a great many of the gastro intestinal complaints of later years would be obviated A good deal of tonsillar disease was preventable with proper treatment of the infant and young child Very many children also suffered from a mild catarrhal cholecystitis and much of that type of disease was preventable also He urged that infants children and young adolescents should periodically be submitted for examination

Mr HAMBLEN THOMAS in reply agreed that preventive treatment was a most important thing and that a number of tonsillar and other conditions could be prevented Dr Maurice Shaw had suggested that the physician had stimulated excessive surgery but the surgeon did look to the physician for his guidance

CALCIUM METABOLISM

At a meeting of the Aberdeen Medico Chirurgical Society on May 5th with the president Mr F K SMITH in the chair Professor DAVID CAMPBELL read a paper entitled

The clinical application of recent studies in calcium metabolism

Outlining the vital importance of inorganic mineral elements in the diet of which calcium is not the least important and the presence of calcium in the tissues of the body Professor Campbell pointed out that the diet was man's only source of calcium and that the minimum daily requirement for an adult was 0·45 gram if active growth was proceeding much more would be required In the absorption of calcium from the gastro intestinal tract the first step was the conversion of the insoluble compounds into a soluble form which was done very efficiently by the hydrochloric acid of the gastric juice Calcium was absorbed only as long as it remained in an acid or neutral medium after which it was precipitated as insoluble compounds and excreted in the stools as phosphates and insoluble soaps It was usually estimated that about 60 per cent of the calcium taken by the mouth was absorbed from the intestine Some of the calcium excreted in the faeces was however re excreted after having been absorbed Turning to the clinical application of these facts the speaker pointed out that Telfer's observations on the mineral composition of human milk which proved it to be closely adjusted to the growth needs of the infant meant that the intake was very little in excess of requirements and that therefore prolonged breast feeding was likely to cause osteoporosis and general stunting of growth from deficiency of lime Secondly if a child were fed during the first few months of life on whole cow's milk there was increase of bone forming elements but there was also considerable increase in the bulk of the faeces leading to an abnormal state of the alimentary canal a faulty absorption of fat and a marked reduction in the absorption of iron owing to the relatively small amount of iron in cow's milk This would apply especially if the child were fed on diluted cow's milk and explained the prevalence of nutritional anaemia in infants and young children The factor which above all others controlled the absorption of calcium and phosphorus in adequate quantity however was vitamin D Professor Campbell illustrated by slides the effect of vitamin D on the excretion of calcium phosphorus and magnesium in the urine and faeces and on the retention of these elements Rickets both early and late and osteomalacia were now recognized to be due to defective utilization of the bone forming elements as a consequence of deficiency of vitamin D Other factors preventing the absorption of calcium from the intestinal canal were coeliac disease with its severe chronic intestinal indigestion and idiopathic steatorrhoea In some cases no cause could be found and the speaker described the case of a man aged 39 years who had pains all over the body with marked decalcification of

most of the bones and spontaneous fractures the serum calcium was 8 mg. per cent. In spite of large amounts of milk, hydrochloric acid, calcium chloride, cod liver oil and ultra-violet ray therapy, no alteration took place either in the serum calcium or the amount of calcium absorbed from the intestine.

Gross overdosage with irradiated ergosterol had been shown to produce decalcification of the bones of the skeleton, and it had recently been suggested that the effect of vitamin D was rather to prevent excretion of calcium by the gut than to increase absorption. The factor regulating the maintenance of the serum calcium level had been shown to be the secretion of the parathyroid glands. If the calcium content of the blood fell, the whole neuro-muscular system became hyperexcitable, the condition known as tetany developing. Professor Campbell described two cases which had come under his observation, illustrating the effects of loss of the parathyroids. Both were cases where the parathyroids had been removed in operations on the thyroid gland. From the metabolic studies carried out on these cases it was found that Collip's parathormone was active in raising the level of the serum calcium, but as a therapeutic measure for use in cases of parathyroid tetany it was ineffective unless given in large and repeated doses. The intravenous injection of 10 c.cm. of a 10 per cent. solution of calcium chloride was an excellent emergency treatment, producing relief of symptoms rapidly, the effect lasting for about a day and a half. It had been found, however, that the best treatment was to present continuously to the bowel large doses of calcium chloride; if this were insufficient, 50 to 100 c.cm. of normal hydrochloric acid along with two litres of milk per diem were added to increase absorption. Both cases had been found to have complete achlorhydria after the operation. It had also been repeatedly noted in both cases that the severity of the symptoms depended upon a slight change in the serum calcium level rather than on the actual level, so that the important thing to know was the direction in which the serum calcium level was moving. Reports of cases of tumours of the parathyroids showed that increased secretion of the parathyroid caused hypercalcæmia, excretion of calcium from the tissues in far larger amounts than the intake, and the condition of generalized osteitis fibrosa. Removal of the tumour caused the serum calcium to fall to normal, and improvement in the symptoms of the condition. There was thus a great storehouse of calcium in the spongiosæ of bone which could be removed by the action of the parathyroid hormone. The important factor in the effective calcium content of the serum was the ionized calcium. Calcium was believed to be present in the serum as a supersaturated solution of acid calcium phosphate, which is relatively insoluble, and therefore poorly ionized. The carbonic acid of the plasma converted this into the more soluble, and therefore better ionized, calcium bicarbonate and calcium hydrogen phosphate; thus a tendency to the alkalotic state would render the calcium less soluble. Clinical illustrations of this were to be seen in gastric tetany from excessive vomiting, tetany from hyperpnœa, ingestion of an excessive amount of alkali, and in infancy the convulsions occurring in fever. Professor Campbell was doubtful of the efficacy of calcium therapy in hæmorrhagic conditions where no deficiency of calcium had been proved, and in œdema, urticaria, asthma, and allied conditions, though he stated that it was claimed to be effective in the treatment of lead poisoning, leading to the deposition of the lead in the bones as a harmless temporary deposit. Another use of calcium was in the therapy of milk fever of cows.

The PRESIDENT, Professor L. S. P. DAVIDSON, Dr. McCIE, Dr. JOHN CRAIG, and Dr. LYALL took part in the keen discussion which followed this paper.

Reviews

THE MEDICAL ANNUAL, 1932

Wright's *Medical Annual*[1] has been so long recognized as the leading conspectus of medicine in the English language that it is difficult to realize that it has only been established fifty years. Even the oldest practitioners can now scarcely recall a time when they did not instinctively turn to this book for the latest information on new methods in every branch of medicine. The present edition is entitled the Jubilee Volume, and the publishers in their foreword look back with justifiable pride to the remarkable success of their publication.

Started in 1883 as a modest volume of some 300 pages and printed in Bristol by the present proprietors for a London publisher, it ran an unsuccessful course for the first two years, when it continued existence was threatened by the financial collapse of the publisher concerned. Mr. Hartland S. Wright, one of the then partners (now chairman of directors), had the foresight to see possibilities in the undertaking, and under the new regime, and in collaboration with the late Dr. Percy Wilde, the *Annual* at once began to assume a position of real importance.

The first editor, Dr. Percy Wilde, is described as a man of great vigour of mind, with a distinct bias towards heterodoxy—in other words, he was a homœopath who practised with much success in Bath. He conceived the idea that an annual medical survey could be written which should be committed to no particular system of practice, and should consider critically and impartially every possible avenue of progress. It was Wilde's plan to invoke the aid of any member of the profession to write on such topics as he might be thoroughly qualified to discuss. In this Jubilee Volume there is a complete list of contributors from the beginning, together with a special supplement containing portraits of the three editors who have been connected with the *Annual* and some 200 of the 193 who have at one time or another been contributors. If the *Medical Annual* owes its success to any one feature above others, there can be little doubt that the catholicity in its choice of contributors would constitute that feature.

Wrights of Bristol have been pioneers of illustrated medical journalism in this country, thanks to the discerning zeal of Mr. Hartland S. Wright, who has been intimately associated with the production of the *Annual* from its inception. Now it is announced with regret that he has been compelled to relinquish active work at the advanced age of 83. Dr. Percy Wilde edited the *Medical Annual* from its foundation till 1910, when he was succeeded by Dr. Carey Coombs, who at first acted alone, and since 1919 in conjunction with Mr. Rendle Short. There is little need to dwell at length upon the contents of the present volume, which does not materially differ from its predecessors except that it is rather larger than usual and contains more illustrations than ever before. A novel departure is the inclusion of articles on veterinary surgery and allied subjects, such as distemper, mange, foot and mouth disease, and tuberculosis in animals. Other special articles are those on continued pyrexia and the dysenteries, of its origin and a review from Holland of the present position with regard to the treatment of rheumatic diseases. Cancer and its treatment is discussed in several well-balanced articles which leave no suggestions unconsidered. In general surgery we learn that the modern tendency is to abandon many of the amputation methods that used to be taught in operative surgery classes, and that even Syme's time-*honoured* method is not free from

[1] *The Medical Annual. A Year Book of Treatment and Practitioner's Index.* Fiftieth year. 1932. Edited by Carey F. Coombs, M.D., F.R.C.P., and A. Rendle Short, M.D., B.S., B.Sc., F.R.C.S. Bristol: J. Wright and Sons, Ltd. London: Simpkin Marshall, Ltd. 1932. (Pp. c + 674; illustrated. 20s. net.)

objections In passing there is one fault to find—the authors of this review on amputations must learn that the famous Edinburgh surgeon was Syme not Symes There is an excellent account amply illustrated of the treatment of hand and arm infections based on Kanavel's work this is of the utmost importance to all practitioners and not merely to professed surgeons Recent advances in methods of anaesthesia are clearly and fully described There is no need however to multiply instances of the thorough manner in which the pathways of progress are explored Every reader of Wright's *Medical Annual* knows what to expect and in the Jubilee Volume he will meet with no disappointments

The publishers and editors are to be congratulated on the continued success of this work which we hope will appear for many years to come spreading wisdom and knowledge through the profession at large

DISEASES OF THE KIDNEY

In *Diseases of the Kidney* Mr W GIRLING BALL and Dr GEOFFREY EVANS have attempted as they state in the first sentence of their preface to give an account of kidney disease from the viewpoint of a physician and surgeon in close collaboration Such composite works are not common nowadays despite the increasingly close co operation between physician and surgeon in all branches of clinical medicine referred to by the authors and we find difficulty in foretelling what class of our profession will derive most benefit from this book It will no doubt be widely read both in its medical and in its surgical parts The authors have endeavoured as they say to make the book thoroughly practical The general practitioner will be interested in the brief description of diagnosis and medical treatment rather than in operative methods The pure physician and the pure surgeon will want more than the brief information which the limits of such a book necessarily enjoin The medical student must study the medical and surgical aspects of renal disease quite separately for his examinations This is indeed our chief criticism two books have been compressed into one within a limited space Even the close co operation between a physician and a surgeon each of high reputation cannot overcome this disadvantage Nevertheless we must recognize the careful preparation and selection that have been bestowed upon the work and the pains taken by the authors in compressing the text to eliminate waste words and vague discussions

A few points for criticism may be taken at random in the medical side of the book Some quite important renal conditions—to name two examples anuria and paroxysmal haemoglobinuria—are so briefly discussed that the description is of small value Bacilluria is not actually mentioned as a clinical condition apart from pyelitis while urinary carriers of pathogenic organisms (*B typhosus* etc) are not considered Renal tube casts (not mentioned in the index) are in view of their importance in different varieties of nephritis inadequately described on page 81 The method of identifying doubly refracting lipoid material in casts by crossed Nicol's prisms should be made clear There is of course ample room for individual opinion upon the vexed question of nephrosis as a clinical or pathological entity and the bias of the physician author is evident and quite justifiable But in a textbook of this kind the opposition of such authorities as Christian on the clinical side and Aschoff on the pathological side to the existence of true nephrosis might have been given more prominence Since in any case pure nephrosis is a rare clinical condition in comparison with other medical diseases of the kidney it seems to us that relatively too much space has been given to its description The chapter on hyperpiesia with its three appendices is a good one but mention might have been made of the difference in the prognosis of this disease in men and women as strikingly shown for instance in the figures of Blackford Bowers and Baker (*Journ Amer Med Assoc* February 1st 1930) because this is of great practical importance

The surgical chapters will probably appeal to a large number of readers for they are up to date and give a clear impression of the views of to day even in the short chapter dealing with operations upon the kidney space is found to give a useful survey not only of the standard operations but to discuss briefly but clearly the value of plastic operations upon the renal pelvis in cases of hydronephrosis Chapter III which deals with the examination of a urinary case will be found very helpful to all commencing the study of urology because it is full of detail and thoroughly practical though not all will agree with the view that the use of an irrigator is the safest method of washing out the bladder for cystoscopy Here are also *included some well chosen reproductions of x rays representing* normal and common abnormal pyelograms Renal calculus also is clearly discussed and well illustrated The chapter on hydronephrosis is particularly interesting for the subject is attracting special attention at the present time but the statement that this condition is rarely congenital is surely contradicted by the increasing number of such cases which are demonstrated nowadays in infants and children and also by the frequency with which abnormal vessels clearly congenital anomalies are found in cases of hydronephrosis No one can say either in what manner or how long such an abnormality may take to produce the pelvic distension and renal damage which so often only becomes obvious in adult life

The authors have been very well served by their publishers The paper and printing are excellent and the reproduction of the 8 coloured plates and 169 other illustrations is also first rate The illustrations of pathological specimens (nearly all from St Bartholomew's Hospital Museum) are a notable feature of the book

Diseases of the Kidney By W Girling Ball F R C S and Geoffrey Evans M D F R C P London J and A Churchill 1932 (Pp xiii + 424 169 figures 8 plates 36s)

PSYCHIATRY

HENDERSON and GILLESPIE'S *Text Book of Psychiatry*[3] has already won a foremost place among the many manuals on mental disease and the appearance of a third edition two years after the second affords proof of its continued popularity By adopting a biological standpoint throughout in which mental illness is envisaged as the final product of morbid reactions to environmental stresses the authors have contrived to do equal justice to the medical and social factors involved in its production and by presenting the setting in which a mental breakdown occurs and without which it cannot properly be understood they have succeeded in making their subject a living one The arrangement of the text follows the same lines as in previous editions the grouping of the psychoses being into affective schizophrenic paranoid and organic reaction types The chapter on epilepsy has been expanded and brought up to date and an entirely new chapter on the psychiatry of childhood has been added to the text In addition a summary is given of the more important laws governing mental disorder in the United States and on the Continent

[3] *A Text Book of Psychiatry* By D K Henderson M D F R F P S and R D Gillespie M D M R C P D P M Third edition Oxford Medical Publications London Milford Oxford University Press 1932 (Pp xii + 595 18s net)

When we turn to Dr Wiersma's *Lectures on Psychiatry* we find ourselves on altogether different ground. It is true that the subject-matter is the same, but the mode of treatment is entirely dissimilar. The lectures given by Dr Wiersma in book *represent the* [illegible] psychiatry and neurology in the University of Groningen from 1926 to 1930. They might therefore be thought to provide ample fare for the [illegible] student. And yet although the psychiatrist [illegible] to derive much benefit from the lectures the subject to the mode of presentation, it will be more [illegible] Indeed [illegible] psychologists have [illegible] The *Lectures* are highly [illegible] The author has deliberately omitted all [illegible] and treatment. He has [illegible] entirely his attention mainly on the study [illegible] and the disturbances of perception [illegible] and volition which in differing [illegible] to the [illegible] accompaniment of all the [illegible] From the angle of approach there is much [illegible] He discriminates of temperamental [illegible] to the degree of emotionality is fully [illegible] Nor is [illegible] recorded of investigations [illegible] of fixation and retention of [illegible] In the consideration of the [illegible] the author treats at length of [illegible] methods as aesthesiometry, marking test [illegible] graph and galvanogram—all accompanied by [illegible] chart. The psychoses are discussed [illegible] not so much as clinical entities but as [illegible] phenomena for psychological investigation. Dr Wiersma pays tribute to Freud and to "the psychoanalytic school in the general sense of that word" but there is little indication from the text of any real indebtedness. His conclusion as to the causes of obsessive symptoms is that they are only rendered possible by a low degree of co-ordination:

> As a result of this images force their way from the periphery to the centre and cannot be repressed. They disturb the normal flow of thought which is then no longer free and under voluntary control. The disintegration dissociation or sinking in is thus primary. All the other symptoms are closely related to it.

Such an interpretation of obsessive phenomena leaves their meaning unexplained. A vast amount of painstaking experiment is revealed in these lectures and Dr Wiersma has succeeded in providing his readers with a fund of information of real importance in the investigation of psychotic states.

PHYSIOLOGY OF EXERCISE

Recent progress in the practice and understanding of physical training has been so considerable that for the fourth edition of *Physiology of Exercise* Dr F. A. SCHMIDT, with assistance from Dr KOHLRAUSCH, found it necessary to rewrite his book almost entirely. This edition has now been translated from the German by Dr C. Spath. The book is a considered study of the effects of physical exercise on the growth and development of the body, and of the physiological processes occurring in the different organs as a result of muscular work. Having surveyed the development and proportions of the normal body at different age periods, the author discusses the modifications which can occur as a result of physical training, and stresses the need for consideration of these in childhood and adolescence. In analysing the mechanics of movement a chronophotographic method has been used which makes possible the mathematical calculation of work *done* in motor activities. With patience and thoroughness Dr Schmidt describes what is known *through* physiological research of the actual effect of exercise on the heart, lungs, muscle groups and nerves, and the changes in metabolism occurring during fatigue. Of more general interest is the consideration of how far constitution and physique affect an individual's choice of sport. The so-called asthenic type is not likely to excel in weight-lifting, but may achieve distinction in running or jumping. The wrestler is usually an intermediate type between the pyknic and muscular, and the "well proportioned" is often an all-round athlete. Throughout the book the harmonious development of the body as a whole is insisted upon, and guidance is given in ways of avoiding harmful training. We feel that undue prominence is given to the translator's name on the cover of the book, which at first glance might suggest joint authorship.

SOCIAL INSURANCE

An admirably complete and clear account of *The British System of Social Insurance* will be found in a volume recently published under that title[a] written by PERCY COHEN. In a short introduction Mr Neville Chamberlain describes the book as "exhaustive, lucid and reliable," and these adjectives are excellently chosen to set out its qualities. In his own preface the author says: "Within the compass of a book of moderate dimensions I have endeavoured to set out in language as free from technicalities as the subjects permit the history of the different systems, the salient features of the Acts of Parliament, and their application to the different sections of the population." This has been done, with reference successively to Health Insurance, Widows' and Orphans' Pensions, Old Age Pensions (contributory and non-contributory), Unemployment Insurance, Workmen's Compensation, and Industrial Assurance, with a brevity, accuracy and clarity which is truly astonishing. The sections of most interest to medical practitioners are naturally those relating to National Health Insurance and to Workmen's Compensation, but it would be of great advantage to general practitioners and to some classes of specialists if they were to make themselves acquainted with the main facts stated and described in the other sections also. Each section begins with a short account of the history and development of the social movement to which it relates. Contrary perhaps to what might be expected these accounts are really interesting, and though brief omit nothing of essential importance. Indeed without them it would be very difficult to understand the reason for many of the provisions of the legislative enactments. This is particularly illustrated in the section dealing with Workmen's Compensation. The book is quite up to date, embodying the effect of regulations made only a few months ago—such as those relating to silicosis and asbestosis—and having full descriptive references to the Government Actuary's Report on the Third Valuation of Approved Societies, and to the relevant parts of the May Report and governmental action relating thereto. Clear statements will be found on such complicated or seemingly obscure subjects as "excepted employments" and "exempt persons," on the prolongation of insurance and the extended year, on Class K," and on aged members ceasing to be employed. The only slight omission noticed is that it is within the power of insurance committees to impose on insurance practitioners a lower limit than 2,500 persons, and it would

be desirable whenever this maximum number is mentioned to note that the average number of insured persons on the list of a practitioner is in the neighbourhood of 1 000 and that the ordinary or general number is less even than this The book can be very highly recommended

NOTES ON BOOKS

The March instalment of the *Annals of Medical History*[1] opens with the first part of Sir Wilmot Herringham's account of the life and times of William Harvey which deals with the first twenty two years of his life and the conditions at the older universities thus expanding Sir Wilmot's Harveian Oration in 1929 on "Circumstances in the life and times of William Harvey" The second and concluding part of Dr Dempster's article on John Locke physician and philosopher is occupied by a reproduction of his *Observationes Medicae* In a well illustrated and attractively written appreciation of Leonardo da Vinci as a physiologist Miss Leona Baumgartner of New Haven has had the advantage of utilizing Professor J F Fulton's library of works bearing on this remarkable genius Leonardo da Vinci's portrait adorns the cover of this instalment and that of Raymond Vieussens appears as the frontispiece thus reproducing the frontispiece of his Neurographia to which Professor R H Major refers in his interesting article on Vieussens and his treatise on the heart In 1929 Dr Joseph Walsh's article showing reason to believe that Galen was born on September 22nd A D 130 appeared in these Annals and was countered by the late Professor Ilberg who argued that the date was a year earlier Dr Walsh in a scholarly documented article now courteously maintains his thesis The origin of the University of Bologna and its history are eloquently related by Dr Giuseppe Franchini of Modena Obstetrics in Mexico before 1600 is the title of an article by Mr Nathan van Patten and Dr D W Montgomery contributes a valuable note on the historical position of *Coccidioides immitis* among the pathogenic fungi of the skin Dr W C Souter's recent account of Harvey in Aberdeen is the subject of a pleasant editorial and there are a number of reviews including one of Dr G C Peachey's *John Heaviside Surgeon*

We learn from the preface to the second edition of the *List of the Transactions Periodicals and Memoirs in the Library of the Royal College of Surgeons*[2] which we owe to the courtesy of the Librarian that the first separate list was first printed in 1890 This second edition which has been prepared for the printer by Mr W A Fusedale contains approximately twice as many entries as the first It runs to 169 pages It is hoped that research workers will avail themselves of this list which is on sale at the College price 2s 6d

VIGNERON'S *Manuel des Calculs de Laboratoire*[3] deals generally with the mathematical problems that present themselves in physical chemical and biological laboratories Treating of such diverse subjects as the theory of errors the calibration of laboratory glassware and the diagrammatic representation of polyphase systems it approaches them from an essentially practical standpoint It indicates the natural sources of experimental error points out the effects of their incidence and shows how to evaluate them and how to derive the due correction The manual is thus not only an aid but also an incentive to accuracy A chapter is devoted to methods by which mathematical solutions may be simplified Another chapter deals exhaustively with the laws of chemical reactions generally and shows how the results of experiment are to be correlated with the laws by which they are governed No extensive knowledge of mathematics is postulated only an elementary knowledge of the principles of the infinitesimal calculus is required on the part of the reader The book is commendably lucid and will prove most useful to those whose work demands experimental accuracy

Italian Medicine[10] is the latest addition to the series of historical medical manuals known as Cho Medica which is appearing under the editorship of Professor E B KRUMBHAAR The present volume is written by Dr CASTIGLIONI the professor of the history of medicine at the Royal University of Padua The book like its predecessors in the series is most readable and is a mine of information packed into 134 pages The long procession of names shows the eminence to which Italians have attained in every branch of medicine Leonardo and Spallanzani Fracastoro and Castellani Morgagni and Theodoric with a host of lesser teachers are known throughout the world and about each of them Professor Castiglioni has something interesting to say In two hours he places his readers in a position and with the desire to go to original sources for further information The editor is to be congratulated upon his successful translation, and the publishers upon their decision to provide a larger number of illustrations than are contained in some of the earlier volumes

PREPARATIONS AND APPLIANCES

SCLERAL MARKER

AN ACCESSORY TO THE IGNI PUNCTURE TREATMENT OF DETACHED RETINA

Dr STEWART MACKY D O M S Western Ophthalmic Hospital N W writes To overcome the difficulty in some cases of marking out the position for the scleral puncture when using the ordinary callipers Amsler devised his set of eleven markers Simple and effective as these are in most cases there still remain a few instances in which the accurate measuring of the distance is a difficult procedure

The fault we find with Amsler's markers is that they are too straight We have overcome this by simply bending the shaft nearly at right angles and find the marker now sits snugly in any position of the eye

Another addition or improvement is that by using a sliding collar and marking the shaft in millimetres we have been able to reduce the number of markers to two (10 to 15 mm and 16 to 21 mm)

The collar also carries a blunt stud which can safely be rested on the limbus when stepping out the distance We find this the greatest improvement Even if (as sometimes unavoidably happens during retraction of the wound) the conjunctiva is drawn up over the limbus this little stud can be slipped under the fold and with a rotating movement a very accurate measurement made This can be done in most instances where the callipers can be used of course but the sharp point always seems to me rather dangerous The simple notch cut on the original Amsler marker needs the most careful adjustment to ensure accuracy especially in those cases where it is difficult to avoid rucking the conjunctiva over the limbus

My thanks are due to Mr J Cole Marshall for his suggestions and for allowing me to try out various modifications in his clinic at the Western Ophthalmic Hospital

Another use of this instrument is the accurate definition of the equator in following Jameson's technique for recession of the recti muscles in cases of squint

Messrs John Weiss and Son Ltd have made this instrument and can now supply it.

THE MILK PROBLEM

The problem of the inadequate supply of good milk is one that has always exercised those concerned with the public health of the country. We do not consume per head of population as much milk as most of our nutritionists—on the evidence it is held, that is not in the best interests of the nation's health. It was stated in Parliament about a year ago that the consumption of milk in Scandinavia is six times as much as that in England and in Canada twice what it is in this country. It may to a certain extent be true that the public has not been sufficiently instructed in the value of milk as a food despite the efforts of health authorities, but this is, however, very little than useless to tell people to "drink more milk" if there does not exist everywhere the power they can afford and work still if much of the milk is not of the best quality. The state of affairs at the moment is clearly set out in the report of the special committee appointed by the People's League of Health to make a survey of tuberculosis of bovine origin in Great Britain.[1] This committee found that 10 per cent. of milch cows in the country are infected with tuberculosis, that 6·7 per cent. of raw market milk contains living tubercle bacilli, and that 2,000 deaths and 1,000 fresh cases of bovine infection, a severely conservative estimate, occur in the population every year. Lord Moynihan declared last year in the House of Lords that over 30 per cent. of tuberculosis in children came from cattle, and that 70 per cent. of non-pulmonary tuberculosis was borne by milk. From these figures it is possible to form some estimate of the amount of disease and crippling which must exist, but which no statistics can accurately measure. It is true that tuberculosis is diminishing, but one of the contributory factors is the devoted effort made during the past ten or twenty years to improve the conditions in which milk is produced and in which the children of the country live. Moreover other diseases are spread by milk—such as diphtheria, typhoid and paratyphoid fevers, scarlet fever, undulant fever, and septic sore throat.

The problem of sufficient milk consumption is therefore the problem of safe milk supply. During the past year several determined attempts have been made to face this question and to set down in black and white its exact scope and the best measures for dealing with it, both immediately and ultimately. The memorandum on bovine tuberculosis in man issued by the Ministry of Health contained much valuable information, and the report of the committee of the People's League of Health also puts forward a detailed and constructive plan which would co-ordinate all existing efforts. So exhaustive has its work been that a Royal Commission, the appointment of which has been suggested would not be likely to add anything of value to our knowledge of the subject and would certainly waste much time and money in covering the same ground. Broadly speaking there are two ways of ensuring a supply of harmless milk. One is to eradicate tuberculosis from dairy cattle, the other is to pasteurize all milk except that produced under ideal conditions from tubercle-free herds. Obviously the former method is hard, the latter comparatively easy. No one taking a long view of the national welfare would however concentrate on the latter and neglect the former. The question is: How to set about the colossal task of eradication and to what extent can the palliative measure of pasteurization be used in the meantime? The committee has given a definite lead towards eradication by recommending three groups of procedures. The first, prophylactic vaccination of cattle, is still in the experimental stage. The second method is to increase the number of tubercle-free herds. The Departmental Committee on the Production and Distribution of Milk which reported in 1919 recommended that official veterinary assistance in diagnosis and eradication should be given, and that certificates should be issued to owners who complied with the necessary conditions, it also urged the establishment of a system of milk grading. The Ministry of Health provided a system of grading in 1922, but the Ministry of Agriculture has given no assistance of the kind recommended. The committee of the People's League of Health is much impressed with the value of such a scheme, and states that cattle-breeders would welcome some indication that the authorities intended to assist them. In recommending measures for the detection and elimination of open cases of tuberculosis, it points out that the Tuberculosis Order of 1925 issued by the Ministry of Agriculture has failed chiefly because sick animals are not detected early enough. It puts forward detailed suggestions for amplifying and improving the Order, and advocates an educational campaign to ensure the good will of the farmers. All its suggestions follow lines already in force, and give a clear lead to those who desire to secure its ends. The Milk (Special Designations) Order, 1923, represents a definite attempt to encourage owners to maintain tubercle-free herds, but is somewhat unsatisfactory. The names are to many persons misleading. 'Grade A,' which anyone might reasonably suppose to be the best, is in fact the lowest of the three; 'Certified' sounds rather like a 'pass degree' but is in fact the highest; "Grade A (T T)" means very little without special explanation. A revised table of designations should clear up these anomalies.

The question of how far to use the immediate measure of pasteurization is a very controversial one. The spread of tuberculosis and other milk-borne diseases from cattle to man can be prevented with practical

[1] *British Medical Journal*, April 9th, 1932, p. 618.
[2] *Ibid.*, 1931, i. 933.

certainty by pasteurization Professor J C G Ledingham, one of the foremost authorities on the laboratory aspect of the problem, thinks that no raw milk is really safe and eminent physicians hold that all milk except certified milk should be pasteurized The arguments on the other side are that pasteurization impairs the value of milk and by rendering dirty and diseased milk innocuous discourages farmers from improving their dairy hygiene or keeping tubercle out of the herds The consensus of opinion is that undesignated milk should be pasteurized but the best means of ensuring that this precaution is practised all over the country is debatable Pasteurization is a precise scientific process laid down in the Milk Order the milk must be exposed to a temperature of between 145° and 150° F for thirty minutes and then at once cooled below 55° It demands special plant and expert attention and is therefore not within the scope of many small producers To make the pasteurization of all undesignated milk compulsory would inflict great hardship on those who cannot afford the plant and staff and would probably cause a serious diminution in the supply besides which such a measure could only be enforced by a larger number of qualified officials than could possibly be made available for some years Dr W G Savage however elaborated some little time ago[1] a scheme for giving the bigger local authorities power to require that all ungraded milk entering their area should be pasteurized Such a scheme would, he claims enable effective supervision to be exercised over the milk supply of large concentrations of people it would provide valuable experience of pasteurization and it would check the practice of treating milk by various heat processes many of them unscientific and casual merely in order to prevent it from going bad It has been adopted by the committee and at present holds the field

The evidence on whether pasteurized milk is as nutritious as raw milk is very conflicting Some workers have shown that pasteurization impairs vitamin C and changes several of the other constituents of the milk, but many physicians children s hospitals and medical officers of health state that milk so treated has a highly satisfactory nutritive value The work of Mr C E Sprawson however recently reported to the Odontological Section of the Royal Society of Medicine - suggests that raw milk has an important factor that pasteurized milk has not Mr Sprawson finds that a daily ration of raw milk given to children will protect from caries any tooth that has not completely formed If this is confirmed current thought about pasteurization will have to be revised its confirmation might have the salutary effect of reinforcing the resolve of the country to purify the sources of its milk We are glad that the committee suggests that the pasteurization of graded milk might be left to the discretion of retailers as a precaution against milk-borne disease and the effects of warm weather and does not propose to follow those authorities who would pasteurize everything but certified milk as a routine measure To do so would in our opinion, stultify the elaborate care with which graded milk is produced Grade A (T T) milk is as safe as is needed for everyday life

PARLIAMENT AND NATIONAL HEALTH INSURANCE

The debate in the House of Commons on the second reading of the National Health Insurance and Contributory Pensions Bill reported in our Parliamentary Notes this week was of much interest The Bill is rendered necessary by certain tendencies revealed at the third valuation of the assets and liabilities of approved societies which if allowed to continue unchecked would endanger, and perhaps destroy the financial stability of the insurance scheme In an article dealing with the results of the valuation[1] we mentioned three major matters in respect to which modifications of the system were urgently called for as being serious handicaps to its successful working These were the superabundance of small approved societies the lack of balance between the benefits to which women were entitled and the contributions made by them and the position of married women within the scheme The first of these points is not touched by the Bill the other two are met by a reduction in the amount of cash benefits in the case of women and especially married women In addition the Bill proposes that arrears of contributions caused by unemployment which since 1928 have been excused in full shall in future be excused only to the extent of one-half the other half having to be met by the insured person himself if he wishes to remain in full benefit The arrangements still make generous provision for the insured person in arrears, both as regards medical benefit and as regards pension rights and even the proposed reduction in cash benefits will leave these at above the pre-war level As the Minister of Health pointed out national health insurance was designed only to provide an assured minimum it did not pretend to provide maintenance for the insured person when out of work not a penny was being taken away from the fund what he was doing was to adjust matters so as to ensure that the money would go round and that the scheme did not break down

The debate showed that the position of the scheme in our national life and the importance of preserving its contributory and insurance character were amply recognized Sir Hilton Young himself described it as 'the prize of our social organization and an example to the world and said that we must maintain the very foundation of the scheme which was that it was a contributory scheme based on the principle that people got what they paid for That was an element

[1] *British Medical Journal* January 9th 1932 p 67

[illegible] [illegible] Mr Rhys Davies [illegible] he is to be attacked towards the medical [illegible] of to be he is in maintaining a [illegible] to find a remedy which has [illegible] to be had to admit that there [illegible] there was not anxious [illegible] the Bill continued to [illegible] insurance [illegible] that now in the future [illegible] and that it was till the [illegible] problem in the world In the [illegible] the Bill did not develop [illegible] Only from the South West of Scotland [illegible] of a consensus of antagonistic [illegible] McGovern and that he and his friends [illegible] with the national health insurance [illegible] doctors and Mr Macquisten [illegible] was angry but with the people [illegible] to the medical profession to becoming [illegible] Mr Maxton however though [illegible] with the opposition thought that [illegible] had been made out It is [illegible] that the Scottish people knew by this time [illegible] importance to attach to such expressions of [illegible] The changes proposed by the Bill do not affect in any way the position of the medical profession or of insurance practitioners in relation to national health insurance but the recognition of that position in the speech of Mr Ernest Brown Parliamentary Secretary to the Ministry of Health and the repudiation by Mr Llewellyn Jones and Dr O Donovan of such attacks as were made upon it nevertheless deserve acknowledgment

One outcome of the statement of the Minister of Health is to make it clear that until the year 1935 at the earliest there can be no legislative proposals for enlarging the scope of the National Health Insurance Acts in any direction that involves increased expenditure or liability He ended at 1935 because there is then due under the statutes a general actuarial survey of all the conditions and circumstances of national health insurance, and that would give an opportunity for reviewing the situation The British Medical Association as representing the profession still stands for an extension of a national health contributory insurance scheme to provide consultant and specialist as well as general practitioner services and to include, broadly and under proper conditions, the dependants of the present class of insured persons and others of like economic status It is more than doubtful, however whether conditions will even by 1936, be such as to allow of so large an extension, and we may note here as a matter of general interest that the Insurance Acts Committee has appointed certain of its members to consider the possibility of extensions of a more gradual character and to open consultations with the Ministry of Health and the Department of Health in Scotland on this subject

INTESTINAL DISEASE AND URINARY COMPLICATIONS

The general impression derived from a combined discussion by the Sections of Urology and Proctology at the Royal Society of Medicine, on May 11th, was that urinary complications are not so common in diseases of the large intestine as might be anticipated In spite of the close proximity and associated function of the urinary and intestinal organs diseases rarely spread from one to the other For instance, in inflammatory and ulcerative lesions of the large intestine it is rare for the infection to pass to the bladder or kidneys It seems in fact that diseases of the large intestine do not predispose to urinary infections unless some definite defect exists in the urinary tract This rule is well exemplified by the urinary infections that result from excision of the rectum At the stage at which carcinoma of the rectum is usually diagnosed less than 3 per cent of patients have an infected urine As a result of injury to the nerve supply of the bladder during rectal excision patients are unable to pass urine naturally for a few days after the operation and during this period or immediately after about 40 per cent of men and 70 per cent of women develop a *B coli* infection of the urinary tract We here have an example of interference with normal function determining infection in an otherwise resistant organ Diverticulitis of the colon is an intestinal disease which is fairly commonly associated with urinary complications The inflammatory thickening of the colon and local peritonitis which accompanies the condition may result in adhesions between the colon and bladder leading eventually to a vesico colic fistula—incidentally a comparatively late complication This disease appears to be the commonest cause of such a fistulous communication between the colon and bladder At an earlier stage of diverticulitis urinary complications may take the form of pericystitis and perivesical abscess both of which cause frequency and perhaps painful micturition In most cases the best treatment for vesico colic fistula is immediate colostomy The opening in the bladder usually closes after the establishment of a colostomy, and the cystitis improves While most surgeons are in favour of this policy the recent discussion showed that some preferred an inguinal and others a transverse colostomy It is to be regretted that better records are not available of the ultimate prognosis in cases of vesico colic fistula, permitting comparison of different methods of treatment

THE ROYAL SOCIETY CONVERSAZIONE

A guest of the Royal Society at one of its conversaziones should be a polyglot for in the plurality of worlds inhabited by men of science strange and diverse languages are spoken Yet to these languages there is a common grammar—the scientific method There is increasing room to-day for the application of this method to medicine, which is becoming more and more of a science and less and less of an art Those who deplore this trend must feel that the President of the Royal Society, Sir F G Hopkins is partly responsible for it through his great work in biochemistry—a science that more than any other has had its repercussions on medicine in recent times Many interesting medical exhibits were shown on May 11th The National

Institute for Medical Research put up an apparatus to demonstrate how crystalline vitamin B is prepared A solution of ergosterol in ether is passed under pressure from purified nitrogen through a silica spiral round a mercury vapour lamp One milligram of the white crystals of calciferol finally obtained represent 40 000 rat doses A series of preparations showed the effect of calciferol in rickets and also the results of overdosage—renal calculi calcification of the vessels of the heart etc Fat removed from vitamin B but having so to say a family connexion with it, was an exhibit illustrating the technical application of x-ray crystal analysis By this method it has been shown that the only crystalline constituent of enamel and dentine is apatite In the enamel these crystals are regularly arranged at an angle to the surface of the tooth their disposition in the dentine is disorderly Great interest was shown in the five exhibits set up by the Imperial Cancer Research Fund Three of these were devoted to the effects of vital staining with trypan blue Fibroblasts of embryonic and adult tissues of the mouse growing *in vitro* segregate trypan blue in the form of granules Malignant fibroblasts (sarcoma cells) do not segregate the dye but are actively phagocytic A series of beautifully stained preparations showed that while mammary gland cells of the mouse stain *in vitro* with trypan blue mammary carcinoma cells do not Similar observations on other types of carcinoma indicate that the failure to segregate acid dyes such as trypan blue is one of the characteristics of cancer cells Another interesting observation was that vital staining with trypan blue reveals no difference between the filterable tumours of the fowl and the malignant tumours of mammals The other two exhibits dealt with the action of radium on malignant growths Irradiation of tumour cells *in vivo* results in an immediate action on the mitochondria which become vesicular Mitosis is inhibited but after an interval the cells increase in size By a series of carefully controlled experiments it has been shown that a therapeutic dose of radium damages malignant cells but that this damage is not sufficient to kill them The regression of a tumour treated by radium is not due to a selective lethal action on the malignant cell but results from the combined injury on the tumour parenchyma and on the tumour bed This injury induces the ordinary processes of repair with invasion of leucocytes and the laying down of fibrous tissue Radium in other words knocks the tumour partly out of action and leaves the body to deal with it after its own fashion Other experiments have shown that the therapeutic effect of irradiation is strictly local there is no general indirect effect on the whole organism Microscopical sections shown by the Lister Institute demonstrated the presence of elementary bodies (Borrel bodies) in fowl pox and the conglomeration of these known as Bollinger bodies The Paschen bodies of vaccinia and variola were also shown Professor Ledingham exhibited specimens of the causative organism of pleuro pneumonia and agalactia As he pointed out at the Royal Microscopical Society [1] the organism of bovine pleuro pneumonia is probably a bacterium or fungus possessing elements so small as to be able to pass through the lower grades of filters An interesting lecture was given by Professor Adrian on the activity of nerve cells and sense organs Brief waves of activity or impulses are discharged in rapid succession down each nerve fibre These impulses give rise to electric charges which can be amplified and recorded During the lecture the discharges of activity from a ganglion in the tail of a water beetle and the arrival of impulses in Mr B H C Matthews's triceps were recorded by a loud speaker Space does not allow comment on other exhibits among which however we must mention one showing the abnormalities induced by the x-ray treatment of the seeds of *Primula sinensis* the inheritance of such abnormalities is being studied Nor must we omit the fossil form Eocarcinus which throws important light on the evolution of the crab from the lobster Eocarcinus was it seems the lobster who decided to become a crab Once more the Royal Society has given its guests an opportunity of getting a glimpse of the intense activity that ceaselessly goes on in the scientific world untroubled by political strife and remote from the vicissitudes of the metal gold

[1] *British Medical Journal* April 30th p 709

THE PARATHYROIDS AND GENERALIZED OSTEITIS FIBROSA

Since Collip's work on the parathyroid gland and his isolation of the hormone in 1925 a great many observations have been made on its physiological properties and on its relation to disease especially certain diseases of bone Secondary hyperparathyroidism occurs in abnormal skeletal conditions such as osteomalacia secondary carcinoma of bone and multiple myelomata, while the hyperparathyroidism of generalized osteitis fibrosa (von Recklinghausen's disease) is now considered to be primary In other words generalized osteitis fibrosa is not strictly a disease of bone but a manifestation of the metabolic disturbances following excessive parathyroid secretion The part played by the parathyroids in this 'disease has been carefully investigated in recent years the work of Donald Hunter[1] in this country affording an excellent example of the way in which medicine can make its contribution to physiology Oversecretion of the parathyroids results in an increased output of phosphorus and calcium in the urine and a hypercalcaemia the most marked feature being the elevation of the blood calcium It has been shown that these calcium salts are derived from the bones The urinary output of calcium in generalized osteitis fibrosa may be as much as six or seven times greater than normal therefore the most prominent feature in the bones is resorption This disease was described by von Recklinghausen in 1891 and distinguished by him from osteomalacia In 1904 Askanazy reported a case in which a parathyroid tumour was found at necropsy It was some time however before the significance of this association was grasped The first operation for the removal of a parathyroid tumour in this disease was performed in 1926 by Mandl of Vienna Since then the existence of hyperparathyroidism has been demonstrated in thirty two cases of generalized osteitis fibrosa in twenty one of which a parathyroid tumour was removed at operation Another case has recently been published by G Gordon

[1] Hunter Donald and Turnbull H M *Brit Journ Surg* October 1931 xix 203

Taylor P Wyatt and S L Baker.[1] In the case one bone in which a fracture of the femur had occurred had previously been amputated at the hip joint on account of suspected malignant growth. The patient was admitted but with fracture of the other femur and the thumb was removed. X-ray photographs taken after the removal of a parathyroid tumour showed increased density of bone and localized appearance of the healed areas of fracture. Next to pain in the case was the relation of the blood calcium at 9·9 mg. per 100 c.cm. [illegible] The author quotes other cases in which a normal blood calcium was associated with severe symptoms and signs of [illegible] pain and tenderness of bones, pathological fractures, thirst and polyuria, hypotonicity of the [illegible] and vomiting.—C. I. Cosin has drawn attention to another—namely excessive growth of hair. The value of clinical research to the understanding of a disease but of normal health is well illustrated by the contributions of medicine to endocrinology. The end of the classroom in this branch of physiology will be manifest in the discussion on the clinical and medical aspects of recent work on bone disease arranged by the Section of Medicine at the Centenary Meeting in July.

ARTIFICIAL PREPARATION OF VITAMIN A

In a letter to *Nature* (May 14th) Dr. J. P. Bowden and Dr. C. P. Snow from the Laboratory of Physical Chemistry, Cambridge, give a short account of experiments they have been carrying out on the vitamins A, B, C, and D. Employing photochemical and spectroscopic methods of chemical analysis they have made several important observations. By these measures they believe they have produced vitamin A artificially. Biological experiments are at present being carried out to confirm this. The method briefly is this (to quote the authors): "The procedure was to study the absorption spectrum of the substance and then to irradiate it with an intense beam of light of similar wave length to that of an absorption band selected after consideration of the spectroscopic data. When applied to a suitable pre-vitamin, monochromatic irradiation with light of the correct wave length produces maximum yields of the vitamin; on the other hand, when the destruction by irradiation of the biological activity of a vitamin is effected by the elimination of an absorption band, the activity can be linked up conclusively with the presence of the band." When a complicated molecule such as a vitamin, is irradiated with rays of varying wave lengths, some of the rays may be decomposing it into different substances while others may be bringing about a recombination of these substances. In the technique adopted by Drs. Bowden and Snow this difficulty is overcome as by means of quartz crystals, they are able to obtain a beam of ultra-violet light of any desired wave length. In this way, by monochromatic irradiation of carotene, they have obtained a substance which absorbs light in a way known to be characteristic of vitamin A. Other important observations have been made on vitamins B_1, C, and D; a fuller account of these experiments will be published later. To quote the authors once more: "It is already clear that irradiation with monochromatic light has very great advantages (as compared with the use of filters) for photochemical experiment in the ultra-violet, especially in the case and certainty with which an absorbing group can be eliminated from a complex organic molecule by irradiation with light of related frequency."

APPLIED PHYSICS OF TO-DAY

As a legacy from the earlier stages of the medical curriculum most of us still possess a few sparks of interest in general science. Perusal of the National Physical Laboratories' annual report for 1931[1] may therefore provide entertaining study for all but a few medical philistines. The space devoted to medicine, which is admittedly small, deals mainly with x-rays, radium, and experiments with dental alloys, fogs, and meat wrappers. It is noteworthy, by the way, for the coining of the new word "spreadability" as applied to butter—hardly a matter for congratulation. The report refers to the internationally recognized and measurable roentgen unit in x-ray dosage, recalls the part played by the National Physical Laboratory in formulating recommendations for the protection of x-ray workers, describes its activities in inspecting hospital x-ray units, and records that four grams of radium have passed through the hands of the laboratory staff for testing during the year. A practical problem was touched in the study of ventilation in long-distance motor coaches, but this appears to have been concerned more with the design of the ventilator than with preventing the entry of exhaust gases. For the rest, the report deals mainly with investigations in the realm of applied physics, a range which includes anything from the design of barges and the resilience of the steel girders used in the British Museum to experiments illustrating the mathematical theory of fluid motion as revealed by the effect of varying wind pressure on the surface of water. Aeronautical science occupies considerable space, and some interesting questions are dealt with. The "wind tunnel" is mentioned in connexion with aerodynamics in general and aeroplane designs in particular, while "spinning" and "buffeting"—the latter a condition of instability due to eddy currents formed in flight—are some of the problems discussed. Among the great diversity of other subjects coming within the ambit of the laboratory are acoustics, wireless, navigation, metal plating, electrical cables, motors and insulators, and the use of x-rays in industry.

[1] The National Physical Laboratory. Report for 1931. London: H.M. Stationery Office. (1s. net.)

We publish in our *Supplement* this week the full provisional programme for the Centenary Meeting of the British Medical Association, together with a list of hotels in London offering accommodation, and other information useful to members who propose to take part in the proceedings. The *Supplement* also contains an abstract of the memorandum on Medicine and the Patent Law, submitted by the Medical Research Council to the Departmental Committee.

The First Hundred Years

NOTES ON THE HISTORY OF THE ASSOCIATION

THE British Medical Association which was founded at Worcester in July 1832 by Sir Charles Hastings celebrates its centenary next July under the Presidency of Lord Dawson of Penn We publish below the sixth of a series of advance extracts from the *History of the Association* which Mr E Muirhead Little F R C S at the invitation of the Council is preparing for publication at the time of the commemorative proceedings in Worcester and London The first article appeared on December 5th 1931 the second on January 2nd 1932 the third on January 30th the fourth on March 26th and the fifth on April 9th

THE ASSOCIATION AND THE POOR LAW

At the Annual Meeting held at Oxford in July 1835 it was unanimously resolved that a committee be appointed to consider the best means of affording medical relief to the sick poor and more especially with reference to the operation of the new Poor Law Act Thus the first shot was fired in the long drawn out battle between the medical profession and the bureaucrats and guardians in which the Association championed not only the rights of the general practitioner but also the best interests of the sick poor

The chief allegations made at this meeting were that many boards of guardians having in view almost exclusively the pecuniary interests of the ratepayers were anxious to simplify their arrangements and adopt the smallest possible expense that in their endeavours to do so they necessarily legislated on medical subjects to the great detriment of the sick poor and to the offence and injury of the professional body—for example the power to decide on the necessity of medical relief is left in a marked way to the discretion of non medical officers Another cause of just complaint was the practice of the boards in some unions of dividing them into districts of great extent comprehending many parishes and a large population all confided to one medical officer thereby placing him at a distance from the sick Delay in attendance must necessarily follow and danger in illness has thereby been increased Moreover in some unions a charge per case had been adopted at the very low rate of 2s 6d varying a little to 3s 6d according as the number of cases in the parish per annum diminished —a case implying any description of illness and of whatever length short of twelve months or any accident requiring surgical attention midwifery excepted—these terms being pressed upon practitioners by threats of the introduction of young adventurers fresh from the medical schools To realize the parsimony and inhumanity of such guardians it must be observed that the charge of 2s 6d was a charge per sick person requiring immediate treatment and not a charge per head of all paupers sick and well

The report of the Poor Law Committee which was read at the next Annual Meeting was printed and published in a separate form and circulated It became and long remained authoritative on this subject The following passage is deserving of reproduction

> The office of parish surgeon should combine the highest qualifications of the medical body it being clear that no professional responsibility whatever public or private equals it in variety or extent It embraces and presents in daily profusion cases in medicine surgery and midwifery requiring as profound knowledge and diligent care as any public institution affords for each of these branches singly *It should unite therefore an acute perception of the incipient stages of disease with well directed efforts for its prevention* accompanied by the most diligent and scientific treatment

The words italicized seem almost prophetic in their wisdom Sir James Mackenzie took the same point of view and urged the same argument in speaking of the role of the general practitioner in our own time

The report did not mince matters It stated that it appeared

> That hardly had the new law come into action when a prejudice was conceived by its administrators against the medical profession and although they were necessarily and totally unacquainted with the various bearing of this important subject not less than with the best mode of effecting an alteration yet in general they distrusted and sternly resisted the suggestions of those who alone were able to assist them—namely the medical practitioners Nothing is more clearly borne out by the evidence your committee has collected than this circumstance though it is gratifying to them to state that in *some unions* and in the sphere of operation of *some assistant commissioners* a more conciliatory spirit has been evinced

Instances were given of cases in which boards of guardians had evinced a desire to meet the fair demands of the professional body and in these cases it had almost invariably happened that the assistant commissioners on the Central Board had refused to ratify the appointments made The degrading system of tender by candidates for Poor Law medical posts was emphatically condemned by the committee

In addition to the grievances complained of at the last Annual Meeting a new one had arisen—that is the institution of medical clubs intended to provide medical relief for two classes of the poor—the independent labourer and the pauper The assistant commissioners in Essex Gloucestershire etc proposed clubs of this kind At Epping the guardians were to have the privilege of adding to the pauper schedule any name they might think proper during the contract paying only at the same rate as for those originally included As the committee remarked such clubs were entirely different from the recently established medical clubs which had nothing to do with pauperism If such clubs were established by the guardians wholesale abuse of the rates would be certain to follow and a position reached similar to that in Ireland in later years where in many places all the population below the gentry were the recipients of gratuitous medical treatment through the Poor Law medical officers who were thus robbed of a considerable part of the income which they ought to have received

The evils of too large medical districts may be exemplified by one case quoted in the report

> In the Wheatenhurst Union comprehending *fourteen* parishes and necessarily much travelling the Commissioners induced the guardians to waive a contract with the established practitioners and to engage *one* young man from the schools who had neither a horse nor instruments

It is noteworthy that in this case as well as many others the authorities in London probably actuated by doctrinaire theories were even worse sweaters than the guardians on the spot who considered their own and their friends pockets After complaining of the indignities often put upon medical officers by boards of guardians the report states

> Those medical men who have presumed to express an opinion unfavourable to the new medical arrangements have

frequently been marked for oppression by the authorities and some have even been induced to withdraw or withhold their names from petitions to Parliament against the system from apprehensions of injurious consequences to themselves

But if the treatment of the profession by the Poor Law authorities was scandalous the treatment of the poor was even more so Sick paupers had in many cases to go long distances to the relieving officer and then to the medical officer should the former in his wisdom think the case a fit one for medical relief

In those unions where a payment per case had been adopted the relieving officer had a stronger inducement to refuse in order than when a contract at a fixed sum existed because by so doing he saved the parish money Several instances have occurred where a disorder in its incipient stage has been denied medical aid because the relieving officer thought the illness not sufficiently serious for attendance Protracted disease or death has occasionally been the consequence

As regards remedies the committee confessed that it was very difficult to suggest any but it plainly stated one great principle that should be observed in future legislation on the subject—namely that the remuneration should not be determined between the interested parties one of which was concerned to reduce it below par and the other to raise it above par A third party should be called in and the scale of remuneration fixed by legislative enactment The committee also recommended the separation of charges for drugs from those for professional services and that wherever possible a dispensary should be fitted up for the supply of medicine to the sick paupers of all the parishes within a reasonable distance at their joint expense while the medical officers should be paid only for the duties which they perform—namely for attendance with a graduated charge for journeys according to the distance and the number of patients It will appear from the above that the chief recommendations of the committee were in principle identical with the arrangements made under the Insurance Act nearly three quarters of a century later with this important difference under the insurance system the doctors are not paid per item but per person on list whether well or ill—obviously more conducive to the encouragement of preventive medicine

It was also resolved at the meeting in 1836 that a petition stating the evils arising out of the Poor Law Amendment Act as regards medical relief and praying for redress should be immediately presented to both Houses of Parliament

A second report of the Poor Law Committee of the Association was made to the Anniversary Meeting at Cheltenham in 1837 and published in volume VI of the *Transactions* The most important recommendations were

That there should be a general professional superintendence of the whole body of union medical officers by a Poor Law Medical Board or by one or more Poor Law Commissioners exercising powers similar to those with which the heads of the Army and Navy medical departments were invested

The committee in a spirit of prophecy looked forward with hope to a period when a Poor Law Medical Board might form a section of a National Board of Health Many things were to happen and generations were to pass away before we the successors of those committeemen were to see this provision fulfilled They repeated their former recommendation that the provision of medicines should be separated from that of medical attendance and they strongly recommended the entire abolition of the system of determining the amount of remuneration by tenders The form and amount of remuneration came in for much discussion which settled down into the recommendation of payment by salary based on a certain percentage of the poor rate in each parish The ratepayers in each parish should elect their own medical officer A petition to Parliament embodying these in the name of the Association was signed by the President

Dealing with the profession itself the Poor Law Committee says

Your committee are led by present occurrences to regret the want of some general discipline some presiding over the members of our profession an influence which is exercised in every profession except the medical It is to be hoped that a higher standard of qualification would ultimately accomplish the desired end but in the meantime something should be done to check the wretched spirit of rivalry speculation the undue bidding and the jobbing which unfortunately are but too frequently to be found among men

In 1842 a special report of the Poor Law Committee of the Association was published in which while congratulating the profession on the measure of success attained the committee discussed the general medical regulations and explanatory circular issued by the Poor Law Commissioners and recommended by the President of the Royal College of Surgeons The following reforms were welcomed (*a*) Tenders for medical attendance were now abolished but it was regretted that the guardians were still left at liberty to fix the price of medicines without reference to any fixed scale or any principle of computation (*b*) Qualifications in both medicine and surgery were henceforth to be required of candidates for union appointments The regulations as to districts of districts were an improvement but were subject to criticism Some areas were much too large The committee urged its objections to the still remaining practice of contracting for medical services

The introduction of a Government Bill for amending the new Poor Law was promised and the committee hoped that the result would be satisfactory if the *principle* on which salaries were to be calculated was to be determined by Parliament The attitude of mind of the Poor Law Commissioners may well be judged from a passage in their Eleventh Annual Report which ran as follows

In fixing this amount [of salary of the medical officers of Poor Law unions] it is necessary that we should keep in view the value at which the services of a medical man are attainable for the purpose under the existing circumstances of the profession

A meeting of medical officers of Poor Law unions with a view to an amelioration of the existing system of medical relief was held in London on October 28th 1847 in which about 200 medical men took part The secretary stated that meetings of medical practitioners had previously been held in various parts of the country to discuss this subject At this meeting it was unanimously resolved that having regard to the nature of the demands made upon medical men charged with attendance on the poor

the scanty remuneration awarded constitutes a grievance which cannot be too strongly stated and for which redress should earnestly be sought [the remuneration] being granted on no fixed principles or scale varies greatly in different localities but that in almost all it is so disproportionately small and in very many of them falls so far short of the expense incurred as to render a large portion of the medical relief bestowed on the sick poor a tax on individual members of the medical profession instead of resting like clothing food and other forms of relief upon the rate paying parishioners in *general*"

A second resolution pointed out that the present system was in the long run uneconomical The Committee had stated in 1839 that the fixed remuneration for permanent paupers in rural districts should be such as to afford the practitioner 6s or 6s 6d a case to be supplemented if necessary up to 10s But the guardians regarded the instructions of the Commissioners—in the Holborn Union the guardians would not pay the medical officers for midwifery cases A committee was appointed by this meeting to watch events and further the interests of Poor Law medical officers This committee and

Convention (as it was at first called) became the Poor Law Medical Officers Association

A deputation from the committee had an interview with the chairman of the Poor Law Commission in April 1848 and submitted fifteen resolutions which were received sympathetically and a month later Sir George Grey received at the Home Office a similar deputation accompanied by representatives from the Royal College of Surgeons of England the Society of Apothecaries the Provincial Medical and Surgical Association and the National Institute of Medicine Surgery and Midwifery (a short lived body long since defunct) Sir George Grey in reply to the arguments adduced by the deputation stated that the question of expense was one subordinate to what was necessary to secure efficient medical relief and that he would confer with the President of the Poor Law Commission

In February 1849 Lord Ashley who had been chairman in 1844 of the committee of the House of Commons on the subject of medical relief to the sick poor presided over a meeting of the Convention of Poor Law Medical Officers at which it was decided to present a petition to Parliament Among other grievances it was pointed out that new sanitary duties had been imposed upon Poor Law officers by the Nuisance Removal and Diseases Prevention Act without the provision of any remuneration

In 1851 a deputation from the Convention had an interview with Lord John Russell at which Sir George Grey was present It presented a memorial setting forth the grievances of three thousand Poor Law medical officers who were responsible for medical attendance on three million poor It concluded by suggesting the following principles 1 Permanence of office during competency and good conduct 2 Remuneration in proportion to the *extent and nature of the duties* 3 *Responsibility to* professional authority under medical inspectors Lord John Russell promised that he would specially communicate with the President of the Poor Law Board with reference to the objects sought by the deputation

In 1854 a committee of the House of Commons which had been appointed to inquire into the mode in which medical relief was then administered in the different unions in England and Wales and to ascertain whether any additional facilities might be afforded to the poor in obtaining medical aid made a report in which it deprecated an entire change in the system as administered under the general consolidated Order of 1847 Although the terms of reference seem to have contained no allusion to the grievances of medical officers some of the recommendations did incidentally bear upon them For instance a reduction of large areas was recommended as were security of tenure of office and increase of inadequate salaries

In 1859 and 1860 the *British Medical Journal* contained many letters and reports of meetings on Poor Law medical reform and a deputation was received by the President of the Poor Law Board A leading article (1860 ii 363) said

> It must be understood that we have to fight the boards of guardians for every penny of increased remuneration we wish to give to the miserably underpaid Poor Law medical officials Those engaged in this struggle should remember that as far as its opponents are concerned the battle will turn upon the mere question of pounds shillings and pence It may be all very well for us to descant upon its human aspect as regards the poor but neither the Poor Law Commissioners nor the boards of guardians will view it for one moment in this light

Mr Piggott's Bill for Reform of the Poor Law as regards medical relief was so strongly opposed—boards of guardians having brought pressure to bear upon many members of Parliament—that he withdrew it

In 1862 the Association drew up a memorial to the Committee of the House of Commons on Poor Relief setting forth the grievances and needs of Poor Law medical officers and making recommendations for their remedy This memorial was signed by Sir Charles Hastings as President of Council and by the General Secretary Dr Philip H Williams and dated from Worcester The committee issued its report in 1864 and the effect of this was discouraging to the friends of the Poor Law medical service In a leading article the *Journal* quoted largely from Mr Richard Griffin's commentary on the report and pointed out that it was hopeless to ask Parliament for redress of grievances In 1868 the columns of the *Journal* were full of letters and reports on Poor Law medical reform and on the grievances of individual officers In this year the Poor Law Medical Officers Association wrote a letter formally asking for the co operation of the British Medical Association It was resolved at the Annual Meeting that a committee be appointed to confer with the council of the Poor Law Association and to co-operate in promoting the interests of reform

The Poor Law dispensary system was the subject of questions in the House of Commons in August 1870 In the same year the *Journal* recorded the fact that a petition to the House of Commons in support of Dr Brady's Poor Law Officers Superannuation Bill was extensively signed and that the Royal College of Surgeons of England presented a petition to the same effect signed by its president and two vice presidents The result was that in the Superannuation Act of that year a clause made it permissible to grant pensions to Poor Law medical officers though it was not until some time later and after much pressure that such officers became entitled to pensions as a right The subject of dispensaries came to the front again in 1872 when the Poor Law Committee reported a conference with the Poor Law Officers Association and the interview of a joint deputation with the President of the Local Government Board Especial attention was directed to the importance of establishing dispensaries and the objections to Poor Law officers as medical officers of health of large districts were pointed out

No great agitation for legal action has since been required but the two Associations have not felt able to relax their vigilance on behalf of the sick pauper and his doctor As medical relief was made more efficient so the cost of pauperism decreased but some boards of guardians were incapable of realizing this fact and persisted in attempts to deprive medical officers of their rights so that from time to time the Association had to intervene In the retrospect for 1884 instances of successful action are recorded but the editor of the *Journal* thus summarized the situation

> In no previous year has there been exhibited by boards of guardians generally so great a disposition to deny their liability and to refuse absolutely to pay extra fees to which medical officers considered that they were entitled and we have further to point out that on appeal to the central department the views of the guardians have either been upheld or it has declined to interfere

The writer concluded by expressing the belief that the only hope of improvement lay in an increase in the number of medical Members of Parliament

In 1885 the disputes which had been frequent as to the disposal and treatment of lunatics in workhouses were settled by an Act which rendered it legal to admit and detain for a certain time persons alleged to be of unsound mind In the same year the disfranchisement of paupers was annulled thus assimilating England with Irish paupers who have never been so disqualified The editor's comment on this was It will be interesting to note whether the English poor will now be less averse from seeking parish relief It now seems doubtful whether the English pauper felt the least interest in the question In the same article it was noted that the abuse of the issue of dispensary tickets in Ireland was carried to such an extent as to annihilate completely all private practice among the small shopkeepers tenant

frequently been marked for oppression by the authorities and some have even been induced to withdraw or withhold their names from petitions to Parliament against the system from apprehensions of injurious consequences to themselves

But if the treatment of the profession by the Poor La v authorities was scandalous the treatment of the poor was even more so Sick paupers had in many cases to go long distances to the relieving officer and then to the medical officer, should the former in his wisdom think the case a fit one for medical relief

'In those unions where a payment per case had been adopted the relieving officer had a stronger inducement to refuse an order than when a contract at a fixed sum existed because by so doing he saved the parish money Several instances have occurred where a disorder in its incipient stage has been denied medical aid because the relieving officer thought the illness not sufficiently serious for attend ance Protracted disease or death has occasionally been the consequence

As regards remedies the committee confessed that it was very difficult to suggest any but it plainly stated one great principle that should be observed in future legislation on the subject—namely that the remuneration should not be determined between the interested parties one of which was concerned to reduce it below par and the other to raise it above par A third party should be called in and the scale of remuneration fixed by legislative enactment The committee also recommended the separation of charges for drugs from those for pro fessional services and that wherever possible a dispensary should be fitted up for the supply of medicine to the sick paupers of all the parishes within a reasonable distance at their joint expense while the medical officers should be paid only for the duties which they perform—namely for attendance, with a graduated charge for journeys according to the distance and the number of patients It will appear from the above that the chief recom mendations of the committee were in principle identical with the arrangements made under the Insurance Act nearly three quarters of a century later with this im portant difference under the insurance system the doctors are not paid per item but per person on list whether well or ill—obviously more conducive to the encourage ment of preventive medicine

It was also resolved at the meeting in 1836 that a petition stating the evils arising out of the Poor Law Amendment Act as regards medical relief and praying for redress should be immediately presented to both Houses of Parliament

A second report of the Poor Law Committee of the Association was made to the Anniversary Meeting at Cheltenham in 1837 and published in volume vi of the *Transactions* The most important recommendations were

That there should be a general professional superin tendence of the whole body of union medical officers by a Poor Law Medical Board or by one or more Poor Law Com missioners exercising powers similar to those with which the heads of the Army and Navy medical departments were invested

The committee in a spirit of prophecy looked forward with hope to a period when a Poor Law Medical Board might form a section of a National Board of Health Many things were to happen and generations were to pass away before we the successors of those committeemen were to see this provision fulfilled They repeated their former recommendation that the provision of medicines should be separated from that of medical attendance and they strongly recommended the entire abolition of the system of determining the amount of remuneration by tenders The form and amount of remuneration came in for much discussion which settled down into the recommendation of payment by salary based on a certain percentage of the poor rate in each parish The rate payers in each parish should elect their own medical officer A petition to Parliament embodying these r in the name of the Association was signed by the Presid

> It must be understood that we have to fight the boards of guardians for every penny of increased remuneration we wish to give to the miserably underpaid Poor Law medical officials The enemy engaged in this struggle should remember that as far as its opponents are concerned the battle will turn upon the mere question of pounds shillings and pence It may be all very well for us to descant upon its humane aspect as regards the poor but neither the Poor Law Commissioners nor the boards of guardians will view it for one moment in this light

Mr Piggott's Bill for Reform of the Poor Law as regards medical relief was so strongly opposed—boards of guardians having brought pressure to bear upon many members of Parliament—that he withdrew it

In 1862 the Association drew up a memorial to the Committee of the House of Commons on Poor Relief setting forth the grievances and needs of Poor Law medical officers and making recommendations for their remedy This memorial was signed by Sir Charles Hastings as President of Council and by the General Secretary Dr Philip H Williams and dated from Worcester The committee issued its report in 1864 and the effect of this was discouraging to the friends of the Poor Law medical service In a leading article the *Journal* quoted largely from Mr Richard Griffin's commentary on the report and pointed out that it was hopeless to ask Parliament for redress of grievances In 1868 the columns of the *Journal* were full of letters and reports on Poor Law medical reform and on the grievances of individual officers In this year the Poor Law Medical Officers Association wrote a letter formally asking for the co operation of the British Medical Association It was resolved at the Annual Meeting that a committee be appointed to confer with the council of the Poor Law Association and to co operate in promoting the interests of reform

The Poor Law dispensary system was the subject of questions in the House of Commons in August 1870 In the same year the *Journal* recorded the fact that a petition to the House of Commons in support of Dr Brady's Poor Law Officers Superannuation Bill was extensively signed and that the Royal College of Surgeons of England presented a petition to the same effect signed by its president and two vice presidents The result was that in the Superannuation Act of that year a clause made it permissible to grant pensions to Poor Law medical officers though it was not until some time later and after much pressure that such officers became entitled to pensions as a right The subject of dispensaries came to the front again in 1872 when the Poor Law Committee reported a conference with the Poor Law Officers Association and the interview of a joint deputation with the President of the Local Government Board Especial attention was directed to the importance of establishing dispensaries and the objections to Poor Law officers as medical officers of health of large districts were pointed out

No great agitation for legal action has since been required but the two Associations have not felt able to relax their vigilance on behalf of the sick pauper and his doctor As medical relief was made more efficient so the cost of pauperism decreased but some boards of guardians were incapable of realizing this fact and persisted in attempts to deprive medical officers of their rights so that from time to time the Association had to intervene In the retrospect for 1884 instances of successful action are recorded but the editor of the *Journal* thus summarized the situation

> In no previous year has there been exhibited by boards of guardians generally so great a disposition to deny their liability and to refuse absolutely to pay extra fees to which medical officers considered that they were entitled and we have further to point out that on appeal to the central department the views of the guardians have either been upheld or it has declined to interfere

The writer concluded by expressing the belief that the only hope of improvement lay in an increase in the number of medical Members of Parliament

In 1885 the disputes which had been frequent as to the disposal and treatment of lunatics in workhouses were settled by an Act which rendered it legal to admit and detain for a certain time persons alleged to be of unsound mind In the same year the disfranchisement of paupers was annulled thus assimilating English with Irish paupers who have never been so disqualified The editor's comment on this was It will be interesting to note whether the English poor will now be less averse from seeking parish relief It now seems doubtful whether the English pauper felt the least interest in the question In the same article it was noted that the abuse of the issue of dispensary tickets in Ireland was carried to such an extent as to annihilate completely all private practice among the small shopkeepers tenant

farmers, and others who in England and Wales have always paid for such medical attendance

In 1892 the Parliamentary Bills Committee made an effort on behalf of the Irish dispensary medical officers 'enabling them to obtain redress for their manifold and serious grievances' In 1894 and 1895 a committee of the British Medical Association made exhaustive inquiries into the nursing in workhouse infirmaries in England and Ireland which disclosed many defects and led to salutary reforms

In 1905 the Poor Law again came to the front when in December of that year a Royal Commission was appointed to inquire into the Poor Laws and the relief of distress As far as it was concerned with medical relief its proceedings were closely watched by the Association which tendered evidence on the subject of the sick poor on whose behalf Dr J C McVail made a careful investigation the results of which were laid before the Commission The abolition of boards of guardians was recommended by both the majority and minority reports of the Commission The former recommended among other things that medical assistance should be reorganized on a provident basis in accordance with the recommendations of the report of the British Medical Association on contract practice and with Dr McVail's special investigation while the latter advocated a whole-time medical service by salaried medical civil servants

As the *Journal* remarked it was a discursive document containing many passages of fervent eloquence even its summary of conclusions reading more like an article in a monthly magazine than the various recommendations of a Royal Commission for fresh legislation Some of the changes which it recommended have since been made such as the formation of a Ministry of Labour one of the duties of which would be to organize a National Labour Exchange There had been nearly one hundred reports to Parliament on Poor Law matters since 1834 but none of them like this including pauperism as a whole

Soon after the earliest reports of the Commission were issued a special Poor Law Reform Committee of the Association was formed which studied the subject and reported from time to time to the Council

The introduction of the National Health Insurance Bill of 1911 diverted attention for a while and dealt with a large part of the field covered by the Commission's researches After the passing of the Act, the war and post war troubles occupied the legislature The formation of the Ministry of Health and the passing of the Local Government Act of 1929 which came into force in April 1930 have deprived many of the recommendations of the Commission of more than historical interest The boards of guardians are now abolished and the administration of poor relief of all kinds placed in the hands of county councils and county boroughs

CONFERENCE ON RADIUM

We have received for publication this week the following report of a conference on radium therapy with special reference to the use of the "four-gram bomb"

This Conference owed its origin to doubts emphatically and publicly expressed as to whether the policy of the Radium Commission was in certain respects mistaken and in particular as to whether its decision to convert the existing single unit (in use at the Westminster Hospital) of 4 grams of radium into four units of 1 gram each was sound There were present

Lord Dawson of Penn	President of the Royal College of Physicians (in the chair)
Lord Moynihan	President of the Royal College of Surgeons
Mr Wilfred Trotter	Representing the Medical Research Council
Sir Frederick Menzies	Chief Medical Officer L C C
Dr Watts Eden	President of the Royal Society of Medicine
Mr H S Souttar	Representing the British Medical Association
Prof Arthur Hall Mr Ernest Miles Prof Woodburn Morison	Representing the Radium Commission

The Conference first considered a memorandum, the salient parts of which are as follows

'What this Conference can usefully do is to consider how far the radium centres within the purview of the Radium Commission with their equipment measures and men, and available funds are at the present time suitable places for the use of the 4 gram bomb

'It is impossible to avoid the conclusion that the benefits from the bomb to patients under conditions existing in the Westminster Hospital have been problematical that the use of the bomb is at present experimental involving considerable outlay of money and that the Westminster Hospital which exists primarily for treating the sick poor does not consider it justifiable to employ its funds in the prosecution of this piece of experimental medicine

When the Conference has heard the evidence on which this conclusion is based it may or may not agree with this conclusion which would not involve condemnation of bomb therapy as such But does it not bring us to this conclusion—namely that the testing out of new methods of radium therapy for example surface radiation and other similar problems requires a special institute staffed by skilled radium therapeutists? England is in serious need at the present time of such a fully equipped radium institute and equally is in need of more skilled radium therapeutists

At the present time we are at serious disadvantage compared with for example Sweden France Belgium etc each of which countries possesses a radium institute well equipped and staffed Our present deficiency in men and means is accounted for by the straitened condition of the national finances The hospitals of this country are having grave difficulty in maintaining their present standard of work and have no money to institute new services

RESOLUTIONS ADOPTED

The Conference next considered written and oral evidence and then after full discussion unanimously passed the following resolutions

1 That in view of all the circumstances this Conference is of opinion that the Radium Commission arrived at a sound conclusion in discontinuing the use of the 4 gram bomb at the present juncture though this decision is without prejudice to the question of the therapeutic value of 4 gram or even larger aggregations of radium

2 That in the opinion of this Conference a fully equipped radium institute is needed in London where the more difficult and speculative problems connected with radium and ray therapy can be studied by the combined efforts of a trained staff

The Conference was in agreement with the Radium Commission that a scientific inquiry on certain aspects of the radium problem would be of value and after discussion unanimously passed the following resolution

3 That in the opinion of the Conference an expert committee should be appointed with the following references (*a*) What is the scientific case for mass radiation by radium and what are the advantages

and dangers attaching to the use of such radiation? (*b*) What are the advantages and risks of massive surface radiation by radium compared with those of radium needles and radon seeds? This committee to obtain any evidence and seek any information which it may think necessary *its proceedings to be private and its report to be made to the Conference*

TECHNICAL COMMITTEE ON MASS RADIATION

The following is the constitution of this technical committee on mass radiation

Lord Dawson of Penn P R C P
Lord Moynihan P R C S

Chairman Mr Henry Souttar

Physics
The Lord Rayleigh F R S
Professor J C M Lennan

Radiotherapy and Medicine
Dr Roy Ward (Radium Institute)
Dr G F Stebbing (Lambeth Hospital L C C)
Dr B W Windeyer (Middlesex Hospital)

Surgery
Mr Cecil Rowntree (Cancer Hospital)
Mr Geoffrey Keynes (St Bartholomew's Hospital)

Gynaecology
Mr Louis Rivett (Middlesex Hospital)
Dr Elizabeth Hurdon (Marie Curie Hospital)

Experimental Radiation
Dr W Cramer (Imperial Cancer Research Laboratory)

ROYAL MEDICAL BENEVOLENT FUND

At a recent meeting the committee voted fifty five grants amounting to £997 Subscriptions and donations are very urgently needed in order that the activities of the Fund may be maintained Legacies are needed to support the Annuity Department Cheques should be made payable to the Honorary Treasurer Royal Medical Benevolent Fund 11 Chandos Street Cavendish Square W 1 The following are particulars of a few cases helped

Daughter aged 85 of M D who died in 1869 at the age of 79 The applicant even at her advanced age is still trying to maintain herself by her own efforts She is assistant organist at the Parish Church and also teaches music to children and by these means earns £22 10s She lives in her own small house and takes in one lodger who pays £27 6s a year Up till recently she let three rooms in her house but the tenant died last year and the applicant has been unable to re let It was discovered that this old lady's total income was £76 16s out of which she had to pay rates of £12 13s Fund voted £26 in four instalments for a period of one year to be renewed annually if circumstances remain the same

M R C S aged 56 married wife aged 59 The applicant had a stroke in the autumn of 1931 and is wholly incapacitated from his professional duties His practice was small and very little is expected from it Private income of applicant and his wife does not exceed £50 a year Fund voted £40 payable in four instalments over a period of one year

Widow aged 59 of M R C S was left penniless by the death of her husband in 1925 At first the applicant took a house and maintained herself by taking paying guests Afterwards she took a post as housekeeper which she retained until her health broke down She has now had to undergo a severe abdominal operation and a medical report states that she will not be fit for remunerative work in the future The applicant therefore becomes entirely dependent on her two daughters aged 30 and 22 both of whom have employment but with small salaries Fund voted £26 payable in four instalments over a period of one year

The Ladies Guild of the Royal Medical Benevolent Fund still receives many applications for clothing especially for coats and skirts for ladies and girls holding secretarial posts and suits for working boys The Guild appeals for second hand clothes and household articles The gifts should be sent to the Secretary of the Guild Tavistock House (North) Tavistock Square W C 1

National Institute for the Deaf

The Lord Mayor Sir Maurice Jenks will preside at the annual meeting of the National Institute for the Deaf at the Mansion House London on Friday May 27th The Archbishop of Canterbury and Lord Charnwood will be the chief speakers The Institute was founded only eight years ago and has already firmly established itself as an indispensable national organization for promoting the welfare of that large section of the community which suffers from deafness in varying degrees Perhaps its greatest success has been in developing a fuller public understanding of the affliction and a deeper and more practical sympathy with those whose lives are burdened by it By setting up counties associations for the deaf the Institute has united public and private effort for their welfare in every part of the country Its services are freely available to the deaf and those interested in them The Institute maintains a home for deaf women a hostel for working deaf boys and a centre of instruction in lip reading for those who have become deaf It takes a strong stand in protecting the deaf from the exploitation of unscrupulous persons who seek to profit by advertising impossible cures or reliefs It encourages and undertakes research in any direction likely to benefit the deaf All this important work of the Institute for a class which has been almost entirely overlooked in the past is too little known

Home Ambulance Service

The thirteenth annual report of the Home Service Ambulance Committee of the Order of St John and the British Red Cross Society for 1931 states that the average number of patients carried annually in each ambulance has increased in the past three years by 12½ per cent This increase in ambulance transport work is attributed to two causes first the change in the social and economic conditions of the country has made it increasingly difficult for patients to arrange for the accommodation of nurses and of all the requisites of the sick room in their own homes This has led to an increased demand for paying wards in hospitals and for nursing homes with a consequent demand for suitable means of transport Secondly radiographic work and treatment by processes making use of special electrical and heating apparatus have become part of the ordinary routine of medical practice and it is on the ambulances of the service that the doctor largely relies for the conveyance of patients to hospitals and clinics where such treatment can be administered Referring to the first aid work of the service the committee states that reports from all parts of the country show that the first aid administered promptly after road accidents has been instrumental in mitigating the more serious consequences of injuries In 1931 in Great Britain there were 24 695 more road accidents and 24 250 more persons injured than in 1930 but the number of deaths resulting therefrom was actually 620 fewer than in 1930 and this the committee suggests may be attributed to the work of the first aid attendants of the service The example set in this country has now been followed in all parts of the world and so important is such a first aid road service considered to be in any ordered road traffic system that a standing international committee has been set up under the auspices of the League of Nations to promote and encourage its development in all countries The Ambulance Committee recognizes that in the event of an epidemic or of a war affecting the civil population the authorities would inevitably look to the Home Service to provide assistance for the sick and injured and the units are applying themselves to the acquisition of a

thorough knowledge of first aid in cases of gas poisoning so that the service may be in a position to render assistance under conditions of chemical warfare The committee regrets that there should be two types of stretcher—the Army type and the Tutley type—but stresses the desirability of ambulances being constructed to accommodate both the long and the short stretcher During 1931 110 895 patients were transported bringing the total number since the service was set up to 1 069 295 Five stations have been equipped since the last annual report and at December 31st 1931, there were 122 ambulances affiliated to the service
